DISCLAIMER

Although the research described in this article has been funded wholly or in part by the United States Environmental Protection Agency (EPA) through EPA-IAG-79-D-X0773 to the United States Fish and Wildlife Service, it has not been subject to EPA policy review and therefore does not necessarily reflect the views of EPA and no official endorsement should be inferred.

PREFACE

Until recently, attempts to monitor the condition of the Nation's waters have focused only on the physical and chemical characteristics of the water, while the components of the biological communities were largely ignored. Additionally, these physical and chemical data were not collected in the context of a statistically designed evaluation. A link between the physical and chemical characteristics and the associated health of the biological communities was clearly needed.

The National Fisheries Survey (Survey) represents the first statistically designed survey of the status of the Nation's waters, their fish communities, and the limiting factors affecting these fish communities. As such, the results of this Survey represent a baseline assessment of the biological quality of the Nation's waters. For the purposes of this report, the Nation's waters are defined as all flowing, freshwater streams and rivers and their associated impoundments in the contiguous 48 United States. Specifically excluded in this definition are wetlands, the Great Lakes, coastal waters, and tidal estuaries. This Survey report can serve as a valuable reference for all agencies responsible for or concerned about the quality of the Nation's waters and their associated fisheries and wildlife. The results presented are the culmination of a 5-year interagency agreement between the U.S. Environmental Protection Agency and the U.S. Fish and Wildlife Service. They are preliminary in that the enormous data base collected by the Survey can be further analyzed to provide additional information on relationships between limiting factors and the sources associated with these factors. The Survey can also be repeated in the future to provide trend data useful in monitoring the status of the Nation's waters.

This report is the first in a three-volume series and is intended for use by professional fishery biologists and water quality management personnel; Federal and State decisionmakers and planners; and the general public. Volume II contains information on the statistical design used to select the Survey sample and to analyze the data (Glauz, W.D. 1984. 1982 National Fisheries Survey. Volume II: Survey design. U.S. Fish Wildl. Serv., FWS/OBS-84/14. 77pp.). Volume III contains the detailed implementation plan used to conduct the Survey (Judy, R.D., Jr. and P.N. Seeley. 1984. 1982 National Fisheries Survey. Volume III: Survey protocol. U.S. Fish Wildl. Serv., FWS/OBS-84/07. 43pp.).

The reader should keep in mind specific programs and agency needs relevant to this Survey and the fact that the Survey is intended as a National assessment. State-by-State and regional comparisons can not be made. In light of the results presented with this report, additional analyses of the data would be desirable and are strongly encouraged.

EXECUTIVE SUMMARY

This report presents initial results of the National Fisheries Survey, an assessment of the biological condition of the Nation's waters conducted jointly by the U.S. Environmental Protection Agency (EPA) and the U.S. Fish and Wildlife Service (FWS) in 1982. Sport fish species, Federally-designated threatened and endangered fish species, and State-designated fish species of special concern were used as indicators of biological status. For the purposes of this Survey, the Nation's waters were defined as all flowing waters in the contiguous 48 United States, including main stem impoundments but excluding the Great Lakes, estuaries, coastal waters, and wetland areas.

The Survey was based on a statistically selected sample of 1,303 river segments from across the Nation using a questionnaire developed by the EPA, the FWS, and their contractors. The respondents were State fish management experts with an average of 9 years of experience in the selected cataloging units or watersheds. An assessment of the fisheries information collected shows that 40% of the reaches had been quantitatively or qualitatively sampled. Sampling occurred in surrounding cataloging units for an additional 33% of reaches. Twelve hundred and eighty-five questionnaires, 98.5% of the total distributed, were completed and returned to the Survey project team. The Survey design, the probability structure used to select the sample reaches, the experience level of the respondents, and the high response rate combine to provide reliable estimates of the status of the Nation's waters, accurate appraisals of their ability to support fish communities, and informed judgements on limiting factors affecting those fish communities.

The respondents were asked to provide information on four basic issues: the fish species occurring in each reach; the time of year during which the segment is usable as fish habitat; conditions adversely affecting fish in the reach; and trends in reach conditions. The respondents also described what kinds of fisheries data were available for the reach. In the analysis, estimates were derived for all waters and for perennial waters only.

This report is the first in a three-volume series and is intended for use by professional fishery biologists and water quality management personnel; Federal and State decisionmakers and planners; and the general public. Volume II contains information on the statistical design used to select the sample streams in the Survey and the analysis of the data. Volume III contains a detailed description of the procedure used to conduct the Survey, including measures followed to ensure consistent handling of data, questions asked, and tracking of questionnaires prior to their return to the Survey project team.

Summary of Survey Results

The Survey is a National assessment and the following facts should be remembered as the Survey results are reviewed:

- The Survey results are presented as National level estimates and no State-by-State comparisons can be made.

- The Survey results are based only on the Nation's flowing waters and associated impoundments. The Great Lakes, estuaries, coastal waters, and wetlands were not included.

- The respondents were experienced fishery biologists.

- The focus of the Survey was the fish community and associated habitat.

- The Survey results must be evaluated within the context of the questionnaire.

- The Survey results are preliminary. Further analyses of these data are necessary to establish definitive relationships between characteristics.

Estimates derived from the Survey responses to a variety of different questions about fish populations, limiting factors such as water quality problems which affect those fish populations, and overall assessments of reach conditions, were found to largely confirm each other within an acceptable margin for error. The picture which emerges from these responses is of waters which, to a large degree, are able to support viable fish populations but which are nevertheless widely affected by pollution, especially from nonpoint sources, and by problems with water quantity, primarily natural low flows. Specific highlights of the Survey results are as follows:

Fish Distribution: Sport fish species which are generally thought to be intolerant of poor water quality are widely distributed, occurring in an estimated 73% of the Nation's waters. Anadromous sport fish species, such as salmon and steelhead trout, occur in 11% of the total stream miles. Commercial fish species occur in 17% of all waters, indicating that freshwater commercial fish populations are an important part of our overall aquatic resources. Nonsport fish species occur in 68% of the Nation's waters, with nonsport anadromous species, such as shad, occurring in only 2% of the total stream miles. Sport fish are abundant in 23% and common in 41% of all waters. The majority (67%) of streams are presently suitable as sport fish habitat.

Results of the Survey show that the two most prevalent sport fish species are the largemouth bass (Micropterus salmoides) and the rainbow trout (Salmo gairdneri), which occur in approximately half of the Nation's waters. The current distribution of these two species may be a result of intensive stocking efforts used in the past to broaden their ranges.

An attempt was made to determine whether sport fish occurrence was restricted to a portion, e.g., upper 25%, of each sample reach. In general, it was found that if sport fish occurred anywhere within the reach, they were distributed throughout the entire reach.

Overall, fish stocking to enhance or maintain sport fish populations does not presently occur in many of the Nation's waters. Less than 10% of the Nation's streams are being stocked at this time. Present stocking relies primarily on fingerlings and catchable-sized fish. Fingerlings are stocked in 8% of the streams, compared to catchable-sized fish in 7% of the streams.

The common carp (Cyprinus carpio), an introduced species, is the most prevalent nonsport fish species. Carp occur in 19% of the Nation's waters, followed closely by a native species, the creek chub (Semotilus atromaculatus), which occurs in 18% of the Nation's waters.

Only 0.8% of the Nation's waters contain Federally-designated threatened and endangered species, compared to 2.4% that contain State-listed species of special concern.

Twenty-one percent of the Nation's streams contain no fish. Most of these reaches, however, are dry during part or all of the year. In a normal water year, 69% of the Nation's waters have water usable all year around as fish habitat; 14% are not usable as fish habitat during any part of the year because of low or no flow. The remaining waters are usable as fish habitat during only part of the year, primarily in the spring and summer. Most of the waters that contain fish are used year-round for spawning, hatching, as nursery habitat and for overwintering. Twelve percent of the Nation's waters serve as migration routes.

Limiting Factors Affecting the Fish Community: A significant percentage (81%) of the Nation's fish communities are adversely affected by limiting factors which are linked to a variety of sources.

Water quality is reported to adversely affect the fish community in 56% of the Nation's waters. The predominant water quality factors are turbidity (affecting 34% of all waters); high water temperature (affecting 26% of all waters); nutrient surpluses (affecting 13% of waters); toxic substances (affecting 10% of waters); and low concentrations of dissolved oxygen (also affecting 10% of waters). More than one limiting factor can occur in each reach.

The major causes of water quality problems in order of number of stream miles affected are total nonpoint sources, agricultural sources, natural sources, and total point sources. Overall, nonpoint sources contribute to water quality problems in 38% of all waters and are ranked as major concerns in 19% of waters. Twenty-nine percent of all waters are adversely affected by agricultural sources of pollution, which are ranked as major concerns in 17% of waters. Natural sources are the third-ranked contributors to water quality degradation and occur in 22% of all waters.

Point sources of pollution also affect the quality of the Nation's waters. Although municipal and industrial point source dischargers are located on, or have the potential to affect, only about 20% of the Nation's

waters, the Survey found that over 10% of all waters are adversely affected by point sources, and that in 5% of all waters, point sources are ranked as major concerns.

Water quantity problems adversely affect the fish community in 68% of the Nation's waters and 41% of perennial waters. Major water quantity problems include: below optimum flows, occurring in 32% of waters; occasional low flows, occurring in 23% of waters; and excessive flow fluctuations occurring in 17% of waters. Natural conditions are the primary causes of these problems, and affect flow in half of the Nation's waters. Agricultural diversions adversely affect 14% of all waters.

Stream habitat conditions limit the fish community in at least 49% of the Nation's waters. The predominant limiting factors are a lack of adult and juvenile habitat (in 40% of the Nation's waters) and of egg and larvae habitat (in 28% of waters). Other major components of aquatic habitat, such as pools, spawning gravels, overhead cover, and riffles, are also absent or degraded in many waters. Major causes of habitat problems are, in decreasing order of importance, excessive siltation, bank erosion and sloughing, natural causes, and channelization.

Significant limiting factors also occur within the fish communities, including fish kills (15% of waters) and contamination of fish flesh (9% of waters). Probable sources of these problems are natural causes, pesticides, and other noxious or toxic substances.

Reach Conditions and Trends: The respondents were asked to evaluate each sample reach's ability to support healthy, reproducing sport fish populations. It was estimated that 67% of the Nation's waters have at least a minimum ability to support sport fish. Approximately 23% cannot support any fish populations at all. Ten percent are able to support populations of nonsport fish species, which are generally considered to be more tolerant of adverse aquatic conditions. Many of the waters which cannot support fish are intermittent and are not likely to improve.

The Survey was designed to elicit responses concerned with past, present, and future trends in the status and condition of the fish community in each reach. Although the responses were speculative, the resulting information provides insights into the effectiveness and direction of numerous water-related Federal programs.

The ability of the Nation's waters to support sport fish has not changed appreciably during the last 5 years. Overall, 91% of the streams have maintained their ability while 5% have been degraded and 4% have improved. Based on respondent speculations, comparisons with conditions projected 5 years in the future indicate that the Nation's waters may be degraded without controls on man-caused limiting factors that adversely affect fish communities.

These Survey results indicate that there are problems with the Nation's waters even though the majority of these waters presently support fish. Natural causes and agriculturally-related nonpoint sources of pollution appear to be a potential constraint to the continued viability of the sport fish communities.

Recommendations

Recommendations resulting from this Survey focus on additional data analyses that need to be conducted to provide further insight into relationships between sources and limiting factors. Additionally, recommendations are made concerning the use of this Survey methodology in conducting other similar surveys.

CHAPTER 1. INTRODUCTION

This report presents the initial results of a major effort to assess the biological conditions of streams in the United States by examining aquatic habitat and fish communities. For the purposes of the Survey, the Nation's waters were defined as all flowing fresh surface waters of the contiguous 48 United States, including impoundments, ditches, and canals shown on U.S. Geological Survey (GS) 1:500,000 scale Hydrologic Unit Series maps. Specifically excluded were the Great Lakes, wetlands, coastal waters, and estuaries. Approximately 1 million miles of streams served as the universe for the Survey.

PROJECT BACKGROUND

The U.S. Fish and Wildlife Service (FWS) and the U.S. Environmental Protection Agency (EPA) identified the need for a survey, based on existing information, for use in evaluating the biological status of the Nation's waters, pursuant to EPA's responsibilities under Sections 101(a) and 104(a)(5) of the Clean Water Act, P.L. 95-217. In July, 1978, the FWS and the EPA entered into a multiphased, 5-year interagency agreement to determine the availability of biological data and to identify limiting factors affecting aquatic communities. This interagency agreement also provided for the development of a statistical methodology to be used to select rivers of interest and to analyze fisheries data collected on a National scale. The interagency agreement was also the vehicle used for implementing and conducting the Survey. These efforts utilized the River Reach File (RRF) concept which was developed concurrently.

The RRF was developed by the EPA to catalogue all of the Nation's waters by assigning a unique alpha-numeric identifier to each stream segment or reach. The term "reach" refers to that portion of a stream or river which extends downstream from one confluence of a stream, river, or lake to the next confluence. Reaches are defined with reference to the specific map scale cited above.

Water bodies in the RRF were digitized from National Oceanographic and Atmospheric Administration (NOAA) aeronautical charts, labeled, linked hydrologically, and then computerized. Each reach was identified by an 11-digit code with the first 8 digits representing the GS cataloging unit code and the last three the unique river reach code.

An assessment of data availability was the second major task undertaken prior to the development of the Survey methodology. This assessment was conducted at an interagency workshop involving technical experts from State and Federal water resource agencies and universities and was designed to determine the availability of quantitative and qualitative descriptors of aquatic systems. The workshop also defined those descriptors which were desirable and feasible to collect for an assessment of the biological quality

1

of the Nation's waters. Results of the workshop were described in detail in the River Reach Phase II Report: A Standardized Method for Classifying Status and Types of Fisheries (Olson et al. 1981). A series of classification descriptors or criteria were proposed that could be used for classifying status and types of fisheries.

Based on the assessment of data availability, a pilot questionnaire was developed and tested in eight states. The results of the pilot testing were reported in the Draft Reach File Status Report: Pilot Survey Results (Olson and Nystrom 1982). The conclusions were that data availability on fish communities and other stream characteristics varied greatly among States and that the pilot questionnaire was too lengthy to be completed easily by State fishery biologists. The focus on obtaining quantified information for all reaches was dropped because these data were not generally available. A modified, shorter questionnaire that requested the kinds of information generally available in all States was developed. This modified questionnaire (Appendix A) was the basis for the present Survey effort.

THE SURVEY

Objectives for the Survey were developed as a part of the interagency agreement. The objectives were:

- The production of statistically-based estimates of the ability of the Nation's water to support sport fish communities and species of special concern;

- The development of a method to assess fish community conditions that was feasible to implement and practical to use;

- The development of techniques that had Nationwide application;

- The compilation of predominantly existing data (where possible); and

- The development of a system that was amenable to updating and revision on a regular basis.

These objectives were the focus of the Survey and directed the type of data analyses and quality control procedures used.

The Survey used biological conditions as an indicator for several reasons. Presence or absence, abundance, and type of organisms present in a water body can provide useful information from a monitoring and management perspective. Displayed over time, trends in biological conditions can provide decisionmakers with information useful in making changes in management strategies for both fisheries and water quality.

The fish community, and, particularly, sport fish and fish species of special concern such as threatened and endangered species, were selected as the biological indicators for the Survey because they are generally present in most perennial water bodies and they react to changes in water quality, quantity, and other factors by mortality, migration, changes in community composition, and reproductive success. Fish effectively represent the bio-

2

logical community because their presence, abundance, and species' habitat needs reflect the physical and chemical conditions occurring in the water body. Additionally, most State Fish and Game Agencies have concentrated their efforts to acquire data on sport fish populations. Because of their expertise with sport fish species and species of special concern, staff within these agencies were chosen as the Survey respondents.

The Survey is closely related to other programs being conducted by the FWS and EPA. Generally, the relationship is one of data acquisition to support, monitor, and manage the Nation's natural resources. One related activity within the FWS is the National Hunting and Fishing Survey (U.S. Fish and Wildlife Service and U.S. Bureau of the Census 1982), which focuses on the attitudes, activities, and desires of the public with regard to the fish and wildlife resources. Also related are the FWS Regional Resource Plans which, taken together, identify and assign priorities to the Nation's fish and wildlife resource problems and related management efforts. Presently the survey instrument serves as the basic structure for a FWS computerized fishery management tool called the River Reach Fisheries Information System (RRFIS).

The EPA programs that relate most closely to the Survey include the National Water Quality Inventory Report to Congress, which is a compilation and analysis of Section 305(b) reports on water quality conditions submitted to EPA by the States. These reports provide the Congress with a summary of water quality conditions and trends which can be useful in allocating resources for activities mandated by the Clean Water Act. The Survey is also commensurate with an increased emphasis in EPA on the use of biomonitoring for National assessments.

CHAPTER 2. METHODOLOGY

DESIGN OF THE SURVEY

The Survey was designed by the EPA and its contractors to gather infor-
mation on fish communities, limiting factors and associated sources adversely
affecting fish communities, and the ability of the Nation's waters to support
fish communities. Reaches to be sampled were selected from the total number
of reaches using a probability sampling design.

For a complete description of the statistics used in designing the
sample strategy, see Volume II: Survey design (Glauz 1984).

The RRF concept was selected as the sampling frame because it met the
statistical requirements of the survey design. However, the coverage in the
RRF was inadequate for the purposes of the Survey and it would have been
prohibitively expensive to modify it to the necessary level of detail.
Therefore, a two-stage sampling design was chosen.

The first stage sample was selected from the universe of the 2,101
cataloging units (watersheds) in the contiguous United States. This first
stage universe of GS cataloging units was stratified to ensure a represen-
tative distribution of the sample with the following stratification vari-
ables:

- Large river systems, such as the lower Mississippi and lower
  Missouri River main stems;

- Presence or absence of one or more cities of 100,000 population or
  more;

- Dry or humid ecoregion;

- Percentage of total area in irrigated cropland;

- Percentage of total area in non-irrigated cropland; and

- Percentage of total area in rangeland.

A sample of 302 cataloging units was selected from the 14 strata with
probability proportional to size (total miles of water contained within the
unit) and with minimum replacement. Figure 1 shows the distribution of these
302 cataloging units.

The RRF was expanded for these 302 cataloging units to include all
reaches depicted on the GS 1:500,000 scale Hydrologic Unit Series maps. It
was recognized that the use of such a large scale map could potentially omit

4
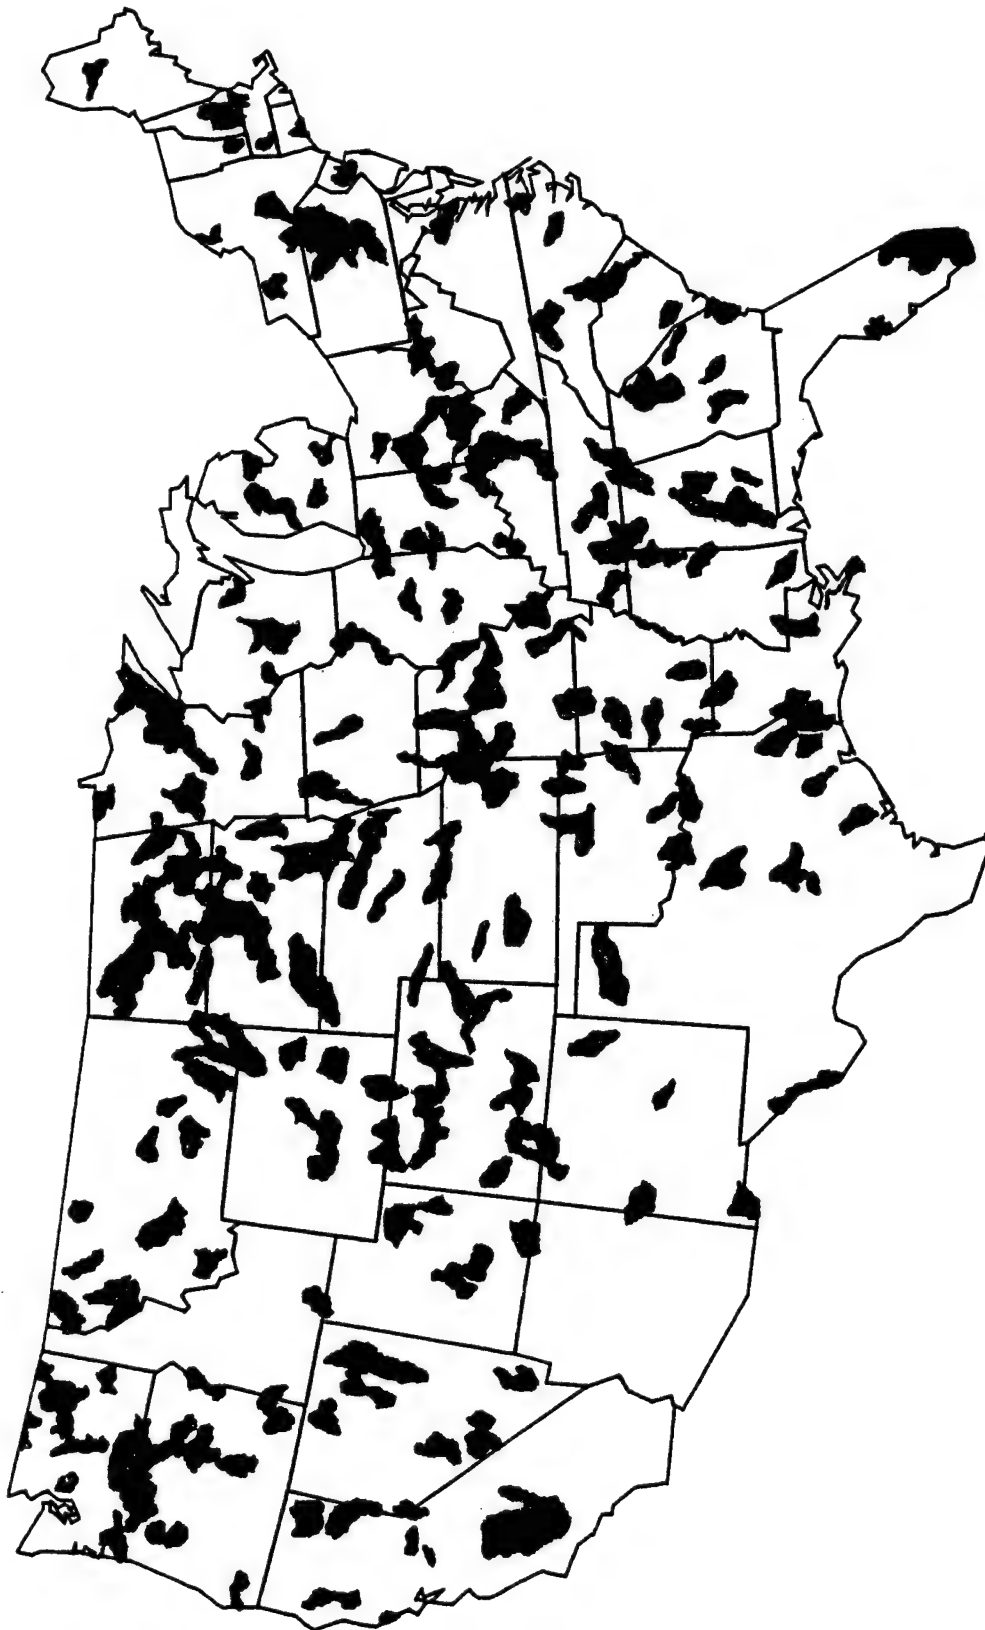

Figure 1. Distribution of cataloging units used in the National Fisheries Survey.

small perennial streams that may contain aquatic life. In order to estimate the percentages and types of streams that could be omitted, Keup (N.D.) compared the results of using 1:62,500 and 1:500,000 scale maps to estimate total stream lengths and volumes. Keup estimated that the 1:500,000 scale maps include between 65% and 75% of the Nation's river surface acres and between 96% and 98% of the total river volume. Because volume is closely associated with available fish habitat, using the RRF at the 1:500,000 scale was not considered to impose an important limitation on the Survey results. This is especially true for a Nationwide assessment.

The second stage of the sample design selected reaches from the first stage sample, again with probability proportional to their size and with minimum replacement. A total of 1,303 reaches were selected, each with a known probability of selection. These reaches represented the ultimate sample of reaches for the Survey.

The Survey questionnaire was based on the results of the pilot test and on input from a committee of biologists, survey statisticians, and questionnaire design experts.

The fish community was selected as the best indicator of biological conditions. Several quantitative measures of the fish community were considered but not used because, based on the vast differences in the fish community Nationwide and the lack of existing data, no one indicator would have resulted in acceptable estimates of the status of the Nation's waters with respect to their ability to support fish.

The final questionnaire (Appendix A) was a mix of questions that closely addressed the objectives of the Survey. The shortened version used in the Survey minimized the burden on the respondents and could be completed with existing information. These two factors were critical to ensuring a high response rate. The Survey questionnaire was also designed to lead each respondent through the questions in such a way that all information necessary to evaluate the conditions within a reach were adequately addressed prior to the actual evaluation of overall condition. The Survey questionnaire was approved by the Office of Management and Budget (OMB) under the Paper Work Reduction Act (OMB Number 2000-0410).

THE SURVEY QUESTIONNAIRE

To assist the reader in following the results, discussions, and conclusions presented in this report, a brief description of each question is presented.

Question 1 requested detailed information on all fish species present, their classes, the life stages that used the reach, their abundance and occurrence in the reach, whether or not they were stocked, and the frequency of stocking.

Question 2 requested information on whether or not the reach and/or surrounding cataloging unit had been sampled qualitatively and quantitatively and the dates of sampling.

Question 3 requested information on whether or not the reach contained water usable as habitat by fish in a normal water year. If it did not contain water all year, the biologist was asked to indicate the months that water was available.

Question 4 requested if the use, survival, or productivity of the fish community was adversely affected by man-caused or natural factors. It also requested information on the limiting factor(s) and associated source(s) that were thought to adversely affect the fish community in the reach. Four general response categories were included: water quality, water quantity, usable habitat, and problems in the fish community. Several limiting factors and sources were listed for each category. If a factor was checked, the biologist was asked to indicate whether it was a major or a minor concern.

Questions 5 through 9 requested the biologist to rate the reach with respect to its ability to support sport fish and species of special concern. These ratings were on a scale from 0 to 5. Zero represented a reach that would not support any fish. A rating of 5 indicated that the reach had maximum ability to support a community of sport fish or species of special concern.

Question 5 requested a rating of the reach at the present time. Question 6 involved ranking of the reach as it was 5 years ago. Questions 7 and 8 requested the respondent to speculate on future conditions in the reach. Question 7 involved a projection of how the reach would be in 5 years if present trends continued. Question 8 involved a projection of how the reach would rank in 5 years if any man-caused limiting factors were controlled. Question 9 asked for a ranking, on the same scale, of the reach in the same or adjacent cataloging unit or watershed that had the greatest ability to support sport fish. Data from Question 9 were not used in the analysis because the biologist's choice was not restricted to the same cataloging unit as the selected reach. Because of the large possible selection of cataloging units adjacent to the selected reach, inconsistencies in responses were noted and any comparative value of the responses was lost. Also, response to this question was below that which was necessary to derive informative estimates.

The analyses of the response to each of the questions asked by the Survey, excluding Question 9, are presented in Chapter 3.

SURVEY IMPLEMENTATION

Implementation of the Survey was dependent on cooperation between the FWS and State fishery management agencies (Appendix B). Care was taken to ensure that as many questionnaires as possible were returned and that questions concerning the Survey were responded to in a similar manner. For a complete description of the Survey protocol, see National Fisheries Survey Volume III: Survey protocol (Judy and Seeley 1984).

Returned questionnaires were edited as described in Volume III. The edited questionnaires were transmitted to the FWS, Western Energy and Land Use Team (WELUT) where the responses to each question were entered into a computer. A copy of the master data tape was sent to the EPA, Washington, DC

for data analysis. <u>A List of Common and Scientific Names of Fishes</u>
<u>from the United States and Canada</u> (American Fisheries Society 1980) was
used to standardize all fish species names. The list of fish species
occurring in reaches sampled by the Survey is included in Appendix C.

DATA ANALYSIS

All data analysis was provided by the EPA and its contractors.
Responses to each question were weighted according to the sample weights
determined by the sampling design used in sample selection. Some modification
of the sampling weights was undertaken to compensate for missing data.
The methods used to analyze the data are described in Volume II of the
National Fisheries Survey (Glauz 1984). Estimates are presented in this
report as the percentage of stream miles nationally.

Two types of data analyses were completed. The first analysis
estimated the occurrence of each parameter of interest in all waters --
perennial and intermittent. The second analysis focused on streams that
were perennial. These two analyses provided for the determination of
conditions on an "all streams" basis and for "perennial streams" only.
Thus, comparisons could be made between "all streams" and streams that
would be more likely to contain fish communities.

The data analysis provided estimates of the extent of a given area
of interest with respect to the overall length of streams. They did not
test for direct cause and effect relationships. The statistical tables
generated during the data analyses are included in Appendix D.

CHAPTER 3. RESULTS

Results are presented as estimates of the percent of total miles of streams in the Nation that possess a given characteristic. Although the term "stream miles" is used here for convenience, these mileages include sections of impoundments, ditches, and canals as well as streams and rivers. Perennial streams were described separately for some questions. The total estimated number of stream miles was used as the denominator in all calculations. Therefore, the estimated results for both "all" and "perennial" streams are a percentage of all streams in the Nation. The estimates of the occurrence of each characteristic include the confidence interval in miles, based on the sampling error in the estimate and the bias potential due to missing data. Because of category overlap and missing data, percentages do not necessarily total 100 percent in all cases.

The following facts should be remembered as the results are reviewed:

- The Survey results are presented as National level estimates and no State-by-State comparisons can be made.

- The Survey results are based only on the Nation's flowing waters and associated impoundments. The Great Lakes, estuaries, coastal waters, and wetlands were not included.

- The respondents were experienced fishery biologists.

- The focus of the Survey was the fish community and associated habitat.

- The Survey results must be evaluated within the context of the questionnaire.

- The Survey results are preliminary. Further analyses of these data are necessary to establish definitive relationships between reach characteristics.

An assessment of the fisheries information collected in the sample shows that 40.0% of the reaches were themselves quantitatively or qualitatively sampled. Where sampling had not occurred specifically in the reach, it did occur in the surrounding cataloging unit for another 33.0% of the reaches. In many cases, these reaches were adjacent to the selected reach segment. The characteristics of these reaches were believed applicable to the selected reach by the questionnaire respondents because of the similarity between fish species and habitat conditions. In the few cases where the respondent had

reservations about applying results from a similar reach in the cataloging unit to the selected reach, surveys were sometimes conducted to determine the biological condition and limiting factors. In total, fish community and limiting factor data had been collected on 73.0% of the selected reaches.

The remaining reaches were not sampled for fish community data, and data on similar reaches in the same cataloging unit were not available. It appears that the lack of data for these reaches corresponds to the fact that they are intermittent streams; State agencies responsible for fisheries management usually focus their resources on perennial streams.

The Survey questionnaire contained three questions related to the respondent's experience. The average fisheries experience of the respondents was 14 years, with a range from 2 to 34 years (Figure 2). Years in the current position ranged from 2 to 32, with an average of 8 years (Figure 3). Experience with streams in the selected cataloging units or watersheds ranged from 2 to 34 years, with an average of 9 years (Figure 4). These overall levels of experience indicate the high level of knowledge of the State respondents and greatly increased the validity of their responses.

QUESTION 1 - THE NATION'S FISH COMMUNITIES

Each respondent was requested to provide information on several aspects of the fish community. This information was used to evaluate the National distribution of fish species, the predominant fish classes (i.e., sport and nonsport), the abundance of fish, and whether or not stocking of the species is occurring on a major scale. The results for Question 1 are discussed based on these subdivisions.

Fish Species Present

Each respondent was requested to provide detailed information on the fish community present in the sample reach. National estimates were calculated for only the 10 most prevalent species for sport and nonsport fish (Table 1). Sport fish were defined as any fish with a legal limit (numbers, weight, or volume) set by the States. A complete list of the 425 fish species recorded present in the selected reaches is included with this report as Appendix C.

Results of the Survey, as shown in Table 1, indicate that the largemouth bass (Micropterus salmoides) and the rainbow trout (including steelhead) (Salmo gairdneri) are the most prevalent sport fish. Largemouth bass are estimated to be present in 27.3% of the Nation's waters while rainbow trout are present in 22.1%. Other prevalent sport fish species, in descending order of abundance, are bluegill (Lepomis macrochirus), channel catfish (Ictalurus punctatus), smallmouth bass (Micropterus dolomieui), green sunfish (Lepomis cyanellus), brook trout (Salvelinus fontinalis), black crappie (Pomoxis nigromaculatus), spotted bass (Micropterus punctulatus), and rock bass (Ambloplites rupestris).

The most prevalent nonsport fish species are the common carp (Cyprinus carpio) and the creek chub (Semotilus atromaculatus), which are present in 19.4% and 18.3% of the Nation's waters, respectively. Other prevalent nonsport fishes include the white sucker (Catostomus commersoni), gizzard shad

Table 1. Ten most prevalent sport and nonsport fish species[a]
occurring in the Nation's waters.

Species	Streams	
	Miles	Percentage[b]
Largemouth bass	263,859	27.3
Rainbow trout	213,461	22.1
Bluegill	188,495	19.5
Channel catfish	148,343	15.4
Smallmouth bass	142,142	14.7
Green sunfish	126,074	13.1
Brook trout	103,507	10.7
Black crappie	98,190	10.2
Spotted bass	98,129	10.2
Rock bass	94,682	9.8
Nonsport Fish Species		
Common carp	187,417	19.4
Creek chub	176,709	18.3
White sucker	166,823	17.3
Gizzard shad	131,730	13.6
Bluntnose minnow	126,665	13.1
Stone roller	122,337	12.7
Green sunfish	115,234	11.9
Common shiner	112,112	11.6
Fathead minnow	110,531	11.4
Golden shiner	106,602	11.0

[a] Additional statistics are presented in Appendix D, Table D-1a and b.
[b] Occurrences were not estimated separately for perennial streams.

14

(Dorosoma cepedianum), bluntnose minnow (Pimephales notatus), stoneroller (Campostoma anomalum), green sunfish (Lepomis cyanellus), common shiner (Notropis cornutus), fathead minnow (Pimephales promelas) and golden shiner (Notemigonus crysoleucas). The green sunfish is considered to be both a sport and nonsport fish species under the Survey definition and, therefore, occurs in both the sport and nonsport fish species lists.

Fish Classes Present

Respondents were requested to list each fish species present and whether they were considered as sport, sport anadromous, commercial, nonsport, non-sport anadromous, nonsport endangered/threatened, or nonsport species of special concern (Table 2).

The results of the analysis of fish class distribution for "all streams" indicate that sport fish species are present in 72.6% of the Nation's waters, with anadromous sport species (such as salmon) present in 10.6%. Commercial species are found in 16.9% of "all streams." Commercial species can include both sport and nonsport fishes under the Survey definition because many states allow commercial fishing (i.e., fishing for profit) for both types of fish.

Nonsport fish species are estimated to occur in 68.1% of the Nation's waters. Nonsport anadromous species (e.g., shad) are present in approximately 2.1% of the streams, indicating that nonsport anadromous species are not widely distributed. Threatened and endangered species and species designated by the State as being of special concern are present in 0.8% and 2.4% of "all stream" miles, respectively. It should be noted that endangered and threatened species in this Survey included only species listed by the FWS under the Endangered Species Act. States are not responsible for sampling Federally-listed endangered species. State-designated threatened and endangered species, if different from the Federal species, are grouped as species of special concern. It was assumed, prior to the Survey, that these species would be nonsport fish under the Survey definition. However, many of the salmonid or trout species of State concern in the western United States are also sport fish. For example, Colorado River basin States classify the Colorado River cutthroat trout (Salmo clarki pleuriticus) as both a game fish and a threatened species.

Twenty-one percent of "all streams" are classified as containing "no fish." The category "no fish" is rarely found in perennial streams (1.9%). The difference in the "no fish" distribution is due largely to the lack of water in intermittent streams. Data for "perennial streams" show a similar distribution of fish classes as "all streams," except for the "sport fish" and "no fish" categories. "Sport fish" occur in 65.9% of "perennial streams" miles, a difference of approximately 7.0% from the "all streams" value.

Reach Use by Fish Class and Activity

Species are not reported individually with respect to reach use in this report. Rather, they are segregated by the major fish classes of sport and

Table 2. Occurrence of fish by class in the Nation's waters.[a]

Fish Class	All Streams		Perennial Streams	
	Stream Miles	Percentage	Stream Miles	Percentage
Sport Fish	701,780	72.6	636,260	65.9
Anadromous sport fish	102,145	10.6	100,216	10.4
Commercial fish	163,005	16.9	153,377	15.9
Nonsport fish	657,606	68.1	582,895	60.3
Anadromous nonsport fish	20,198	2.1	19,540	2.0
Threatened/Endangered fish	7,720	0.8	7,720	0.8
Species of special concern	23,204	2.4	21,450	2.2
No fish	204,074	21.1	18,298	1.9

[a] Complete Statistics are provided in Appendix D, Table D-2a and b.

nonsport (Table 3). No separate analysis of "perennial streams" was conducted for this category. Use, in this context, refers to biological activity such as the following:

- Year-round resident. A fish species that lives and reproduces in the reach for the entire year.

- Spawns elsewhere. A fish species that lives in the reach but leaves the reach for the purpose of spawning.

- Spawning and hatching. A fish species that lays eggs in the reach. The rest of the life cycle is completed elsewhere.

- Nursery. A fish species that uses the reach as an area for rearing its young.

- Migration route. The fish species uses the reach as a corridor to another area for the purpose of spawning or other life cycle stages.

- Overwintering. The reach is used by the fish species as a wintering area.

Table 3. Estimates of reach use by fish class[a].

| Reach Use | Stream | |
	Miles	Percentage[b]
Sport Fish		
Year-round resident	633,635	65.6
Spawns elsewhere	96,413	10.0
Spawning/hatching	657,376	68.0
Nursery	653,968	67.7
Migration route	115,184	11.9
Overwintering	640,921	66.3
Nonsport Fish		
Year-round resident	600,946	62.3
Spawns elsewhere	65,553	6.8
Spawning/hatching	616,794	64.0
Nursery	611,247	63.4
Migration route	37,956	3.9
Overwintering	602,539	62.5

[a]Additional statistics are presented in Appendix D, Table D-3a.

[b]Data for "perennial streams" were not analyzed.

In general, reach use by year-round sport and nonsport fish classes is approximately equal to or less than the values for fish class distribution. Sport fish occur year-round in 65.6% of the Nation's waters. This value is exceeded by the number of miles used for spawning and hatching (68.0%) and as overwintering habitat (66.3%).

Nonsport fish are year-round residents in approximately 62.3% of "all streams." Spawning/hatching and nursery areas are represented by 64.0% and 63.4% of all miles, respectively. Nonsport fish overwinter in approximately the same number of miles of streams (62.5%) as nonsport year-round residents (62.3%).

Fish Class Abundance

The abundance of sport and nonsport fish was analyzed both for "all streams" and for "perennial streams" (Table 4). No single quantifiable description of abundance was possible because of the variability that exists in different types of streams in different parts of the Nation and in the types of data collected by each State (Olson and Nystrom 1982). Subjective descriptors of abundance included abundant, common, uncommon, rare, expected, and unknown.

Table 4. National estimates of fish class abundance for "all streams" and "perennial streams"[a].

Fish Class Abundance	All Streams		Perennial Streams	
	Stream Miles	Percentage	Stream Miles	Percentage
Sport Fish				
Abundant	221,694	23.0	208,263	21.6
Common	391,757	40.6	354,024	36.7
Uncommon	52,582	5.5	45,118	4.7
Rare	12,228	1.3	10,196	1.1
Expected	65,619	6.8	59,984	6.2
Nonsport Fish				
Abundant	334,700	35.1	306,363	32.2
Common	303,713	31.9	270,771	28.4
Uncommon	22,344	2.3	13,874	1.5
Rare	4,727	0.5	3,758	0.4
Expected	60,414	6.3	53,286	5.6

[a]See Appendix D, Tables D-4a and b for additional statistics on these fish class abundances.

In "all streams," sport fish are abundant in 23.0% of the stream miles and common in 40.6% Therefore, 63.6% of the Nation's waters are suitable as sport fish habitat. Waters in which sport fish are uncommon or rare are 5.5% and 1.3%, respectively. The respondents expect sport fish species in an additional 6.8% of "all streams."

18

Nonsport fish in "all streams" are estimated as abundant in 35.1% of the stream miles, common in 31.9%, uncommon in 2.3%, rare in 0.5%, and expected in 6.3%.

"Perennial streams" exhibit similar fish use characteristics as do "all streams," although all values for occurrence and percentages are slightly less. These data suggest that none of the fish classes occur in intermittent streams to any great degree.

Percentage of the Reach that Supports Fish

The analysis of the percentage of the reach that supports fish focused entirely on sport and nonsport classes of fish (Table 5). These results indicate that if fish are present they generally occur in 100% of the reach. Additionally, these results strongly suggest that river reaches are good sampling units regarding the fish community. In the analysis, "all streams" have a greater percentage of streams not supporting fish than do "perennial streams," which may be due to the influence of considering intermittent streams.

Table 5. Estimates of the percentage of each reach that supports sport and nonsport fish classes[a]

| | Percentage of Reach that Supports Fish | | | | |
	0	1-24	25-49	50-74	75-100
All Streams					
Total Sport Fish (percent)	35.4	3.3	3.8	9.9	47.6
Total Nonsport Fish (percent)	36.0	1.6	1.9	7.6	53.0
Perennial Streams					
Total Sport Fish (percent)	13.3	2.1	3.5	8.5	44.9
Total Nonsport Fish (percent)	12.5	0.9	1.0	6.6	48.9

[a]For additional statistics on estimated percentages, see Appendix D, Tables D-5a and b.

Fish Stocking

Each respondent was requested to provide information on whether or not the species listed are stocked and, if so, the life stage stocked and frequency of stocking. Stocking has often been used as a management tool to provide sufficient numbers of fish for harvest by both commercial and sport fishing interests. It was assumed that, except for experimental programs, stocking was directed at sport fish species (Table 6).

19

Table 6. National estimates of fish stocking programs for all streams[a].

Life Stage Stocked	Stream Miles	Percentage
All Streams		
Sport Fish		
Eyed eggs	0.0	0.0
Larvae	786	0.08
Fingerlings	78,596	8.1
Subcatchables	15,424	1.6
Catchables	65,186	6.8
More than one life stage	19,520	2.0
Nonsport Fish	0.0	0.0
Perennial Streams		
Sport Fish		
Eyed eggs	0.0	0.0
Larvae	786	0.08
Fingerlings	73,978	7.7
Subcatchables	15,424	1.6
Catchables	64,235	6.7
More than one life stage	19,520	2.0
Nonsport Fish	0.0	0.0

[1] Complete Statistics are given in Appendix D, Table D-6a and b.

Data indicate that present stocking programs rely heavily on fingerling and catchable-size fish. Eight percent of "all streams" and 7.7% of "perennial streams" are stocked with fingerlings. Seven percent of "all streams" and 6.7% of "perennial streams" are stocked with catchable-size fish. All other life stages stocked are less than 2.0%. No major differences in life stage of fish stocked exist between "all streams" and "perennial streams."

Stocking frequencies were divided into three categories: (1) less than once annually; (2) annually; and (3) more than once annually (Table 7). For those waters that are stocked, stocking rarely occurs more frequently than once annually.

Table 7. National estimates of frequency of stocking for maintenance of sport fish species[a].

Stocking Frequency	Stream Miles	Percentage
All Streams		
Sport Fish		
Less than once annually	64,906	6.7
Annually	71,798	7.4
More than once annually	30,040	3.1
Nonsport Fish	0	0.0
Perennial Streams		
Sport Fish		
Less than once annually	63,342	6.6
Annually	68,014	7.0
More than once annually	29,089	3.0
Nonsport Fish	0	0.0

[a]Additional statistics are in Appendix D, Tables D-6a and b.

QUESTION 2 - FISH COMMUNITY SAMPLING EFFORTS

No comparisons were made between quantitative and qualitative fish sampling in "all streams" and "perennial streams." The sampling effort appears to have been approximately equal between quantitative and qualitative methods. Thirty-one percent and 24.6% of the Nation's waters were sampled quantitatively or qualitatively for fish, respectively. Twenty-eight percent had definitely been qualitatively sampled for fish, while 2.9% were thought to have been qualitatively sampled. Respondents reported reaches to be definitely sampled if records existed, and thought to have been sampled if they were part of a river system that had been sampled for fish. Because some of the reaches were sampled by both quantitative and qualitative methods, the total percentage of reaches sampled for fish is approximately 40%.

21

QUESTION 3 - WATER AS USABLE FISH HABITAT

A determinant of the distribution of fish species is the amount and quality of usable stream habitat. A major component of fish habitat is stream flow (Tennant 1975). Each respondent was asked to indicate the months that the reach had water usable as fish habitat during a normal water year (Figure 5).

Sixty-nine percent of "all streams" contain year-round fish habitat. Streams with no usable habitat during the entire year account for 14.1%. The remainder are waters suitable as habitat during part of the year, with the majority having water during March, April, May, and June, probably the result of spring rains and snowmelt.

QUESTION 4 - FACTORS AND SOURCES ADVERSELY AFFECTING THE FISH COMMUNITY

Each respondent was asked to indicate whether or not the survival, productivity, or use of the reach by the fish community was adversely affected by natural or man-caused conditions. These conditions were grouped into four general categories: water quality, water quantity, usable habitat, and the fish community (Table 8). A list of limiting factors for each category was included. The respondent was also requested to indicate whether the appropriate limiting factors were of major or minor concern.

Table 8. Estimated distribution of major classes of problems adversely affecting fish in the Nation's waters[a].

Class	All Streams		Perennial Streams	
	Stream Miles	Percentage	Stream Miles	Percentage
Water Quality	535,084	56.0	433,987	45.4
Water Quantity	649,102	68.0	387,874	40.6
Usable Habitat	464,885	48.7	387,024	40.5
Fish Community	309,630	32.4	261,018	27.3
Total Adversely Affected	773,330	81.0	508,332	53.3
No Adverse Effects	180,327	18.9	157,831	16.5

[a]Additional statistics are in Appendix D, Tables D-7a and b.

It is estimated that 81.0% of the Nation's waters have fish communities that are adversely affected by a variety of factors. These include water quality in 56.0%, water quantity in 68.0%, usable fish habitat in 48.7%, and problems in the fish community in 32.4% of the Nation's waters.

Data indicate that a smaller number of "perennial stream" miles are adversely affected by all problem categories than are "all stream" miles. The major differences between "perennial streams" and "all streams" are in the miles affected by water quality and quantity problems. These differences are generally attributable to low water flow in intermittent streams.

22
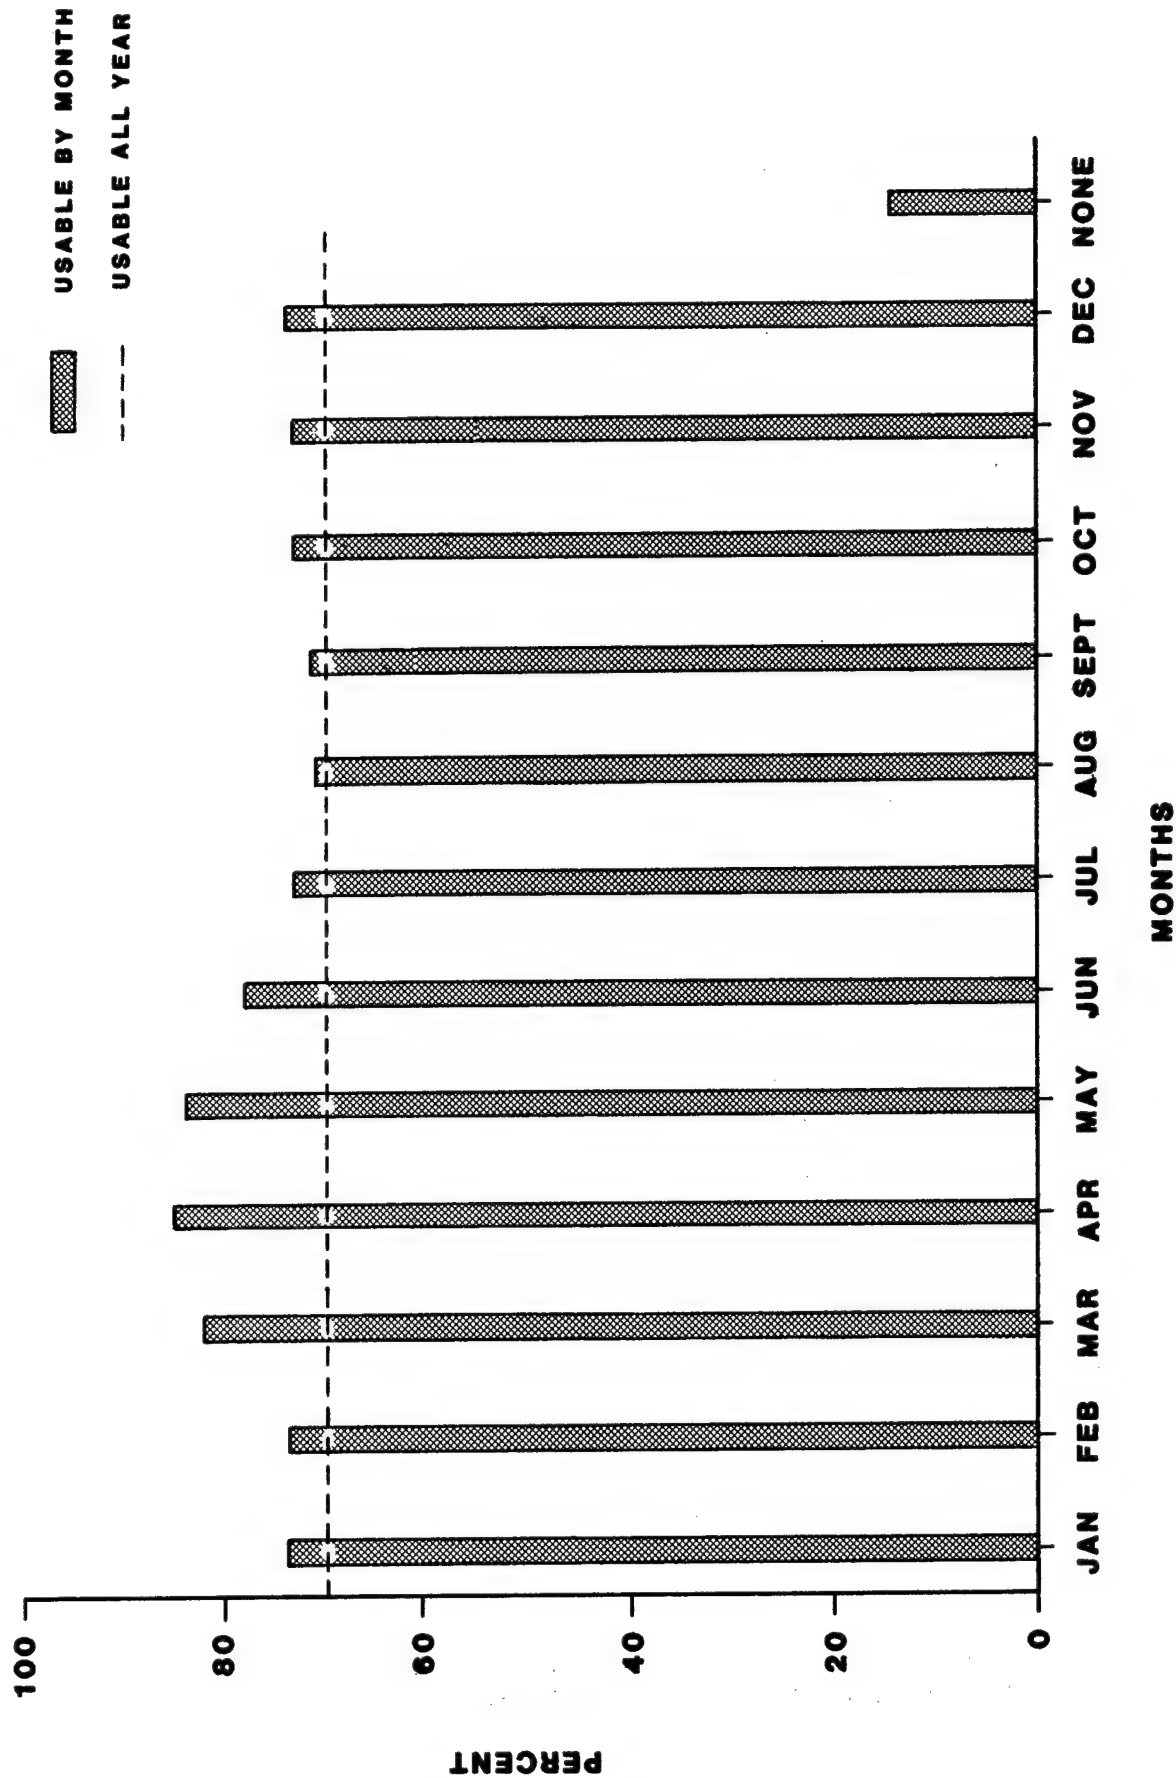

Figure 5. Months of usable habitat.

Because many intermittent streams had not been sampled, the respondents were asked whether or not they definitely knew a problem existed or if the problems were suspected. Results of this analysis show that, in all cases, problems that were definitely known to exist affect a larger percentage of stream miles than those suspected in both "all streams" and "perennial streams" (Table 9).

Table 9. Estimates of the respondents' confidence of the occurrence of major problem classes as percentages of the total stream miles[a].

Class	All Streams Percentage	Perennial Streams Percentage
Water Quality (Definitely)	34.4	26.3
Water Quality (Suspected)	21.6	19.1
Water Quantity (Definitely)	49.2	26.0
Water Quantity (Suspected)	18.8	14.6
Usable Habitat (Definitely)	30.3	24.3
Usable Habitat (Suspected)	18.4	16.2
Fish Community (Definitely)	21.1	17.3
Fish Community (Suspected)	11.3	10.0

[a]Additional statistics are in Appendix D, Tables D-7a and b. The percentages presented in Tables D-7a and b represent the additive total for each class.

Water Quality Factors

Respondents were asked to provide information on water quality factors and sources that adversely affect fish communities (Table 10 and Figure 6). Limiting factors were ranked in order from highest to lowest number of stream miles affected and as a percentage of both "all streams" and "perennial streams."

High turbidity conditions occur in 34.4% of "all streams" and 29.0% of "perennial streams." High turbidity (high suspended solids) directly affects fish survival by clogging gill membranes and indirectly affects survival by smothering fish eggs and covering spawning areas. High turbidity can result in increased water temperature, resulting in decreased levels of dissolved oxygen (Hynes 1970).

High water temperatures occur in 26.2% of "all streams" and 19.1% of "perennial streams." High water temperature can affect both cold-water and warm-water fish species. The generally accepted upper limit for cold-water species, most notably trout, is $20^{\circ}C$, while the upper limit for most warm-water species ranges from $30^{\circ}C$ to $35^{\circ}C$ (U. S. Environmental Protection Agency 1976). These upper limits are extremes and are for the most part higher than those needed for optimum growth (U. S. Environmental Protection Agency 1976).

Nutrient surpluses occur in 12.5% of "all streams" and 11.3% of "perennial streams." Nutrient surpluses can adversely affect water quality by contributing to excessive growths of algae and aquatic plants. While these

Table 10. Water quality factors affecting the Nation's fisheries[a].

Factor	Stream Miles	Percentage
All Streams		
Turbidity	328,261	34.4

☐ ALL STREAMS

■ PERENNIAL STREAMS

Figure 6. Water quality factors adversely affecting
fish communities in the Nation's waters.

26

organisms themselves may not be detrimental, the increased consumption of dissolved oxygen (DO) during nighttime respiration, coupled with a concurrent decrease in photosynthesis, can greatly reduce the DO available to fish (Hynes 1970). Nutrients in flowing waters that enter natural lakes or impoundments can cause adverse changes in water quality, termed "cultural eutrophication," that result in the accelerated aging of a standing water body.

Toxic substances occur in 9.8% of "all streams" and 9.1% of "perennial streams." Toxic substances affect fish directly by causing death and indirectly by interference with life functions such as reproduction and growth (U. S. Environmental Protection Agency 1976). Toxic substances include heavy metals, such as zinc and mercury, and organic compounds.

Dissolved oxygen problems occur in 9.5% of "all streams" and 7.9% of "perennial streams." Adequate concentrations of dissolved oxygen are important to fish respiration. Dissolved oxygen problems can result from excessive turbidity, high water temperatures, aquatic plant blooms, or decaying organic matter.

Other limiting factors reported, such as nutrient deficiency, low pH, salinity, and gas supersaturation, each occur in less than 5% of "all streams."

Limiting factors are approximately evenly divided between being considered a major and minor concern for both "all streams" and "perennial streams." Turbidity is a major concern in 16.9% and a minor concern in 17.3% of "all streams." High temperatures are a major problem in 13.7% of "all streams" and a minor problem in 12.4%. Toxic substances are a major concern in 3.6% and a minor concern in 6.2% of "all streams." Nutrient surpluses and dissolved oxygen are also relatively equally divided between major and minor concerns. "Perennial streams" reflect the same trend in distribution of concerns between major and minor for all of these limiting factors.

Sources Associated with Water Quality Factors

Probable sources of adverse water quality factors include a wide variety of point and nonpoint sources. Point sources are defined as originating from a pipe or conduit. Nonpoint sources are all diffuse sources, such as runoff from urban, agricultural, and natural areas. Identified pollution sources were ranked in descending order of frequency by stream miles and by the percentage of all streams affected (Table 11 and Figure 7).

The total nonpoint source contribution accounts for the greatest percentage of water quality problems: 38.4% of "all streams" and 34.6% of "perennial streams." Specifically, agricultural activities are identified as causing adverse effects in 29.5% of "all streams" and 26.3% of "perennial streams." Natural sources adversely affect 22.2% of "all streams" and 15.7% percent of "perennial streams."

27

Table 11. Probable sources of National water quality problems expressed in total stream miles and as percentages of total miles in the Nation's waters[a].

☐ ALL STREAMS

■ PERENNIAL STREAMS

29

Although point sources are located on, or have the potential to affect, only about 20% of the Nation's waters, the survey found that over 12.3% of "all waters" are adversely affected by total point source contribution. Specifically, municipal sources were found to adversely affect 6.7% of the waters and industrial sources were found in 4.9%. Other identified pollution sources each account for less than 8% of the sources of adverse water quality factors in the Nation's waters.

It is estimated that nonpoint sources of pollution are considered a major concern in 18.9% and a minor concern in 15.1% of "all streams." Agricultural sources are ranked as a major concern in 17.3% and a minor concern in 12.1% of the Nation's waters. Natural causes rank as a major concern in 14.2% and as a minor concern in 7.9% of the Nation's waters. Point source discharges are a major concern in 5.0% and a minor concern in 5.6% of the Nation's waters. The pattern of major and minor concerns was similar for "perennial streams."

Water Quantity Factors

Each respondent was requested to indicate whether water quantity was a limiting factor adversely affecting the fish community. The water quantity factors most frequently associated with adverse effects on the fish community in "all streams" are below optimum flows, occasional low flows, and excessive flow fluctuations (Table 12 and Figure 8). Below optimum flows occur in 31.5% of "all streams" and 19.7% of "perennial streams." Occasional low flows occur in 22.6% of "all streams" and 18.7% of "perennial streams." Excessive flow fluctuations occur in 16.6% of "all streams" and 12.4% of "perennial streams." All other limiting flow factors, such as above optimum flows and loss of flushing flows, each occur in less than 10% of both "all streams" and "perennial streams."

The major difference between "all streams" and "perennial streams" is the magnitude of adverse water quantity factors. All water quantity problems and, especially, below optimum flows, occur in fewer "perennial streams" than in the "all streams" category. This is because of the influence of including intermittent streams in the "all streams" category.

Water quantity factors were also analyzed in the context of being a major or minor problem. Data indicate that below optimum flows are rated as a major problem in 22.8% and as a minor problem in 8.6% of "all streams." Occasional low flows are rated as a major problem in 9.0% and a minor problem in 13.5% of "all streams." Excessive flow fluctuations are identified more often as a major problem, 11.5%, versus 5.1% as a minor problem in "all streams." Water quantity limitations in intermittent and dry streams rated as major problems in 9.6% and 5.1% of "all streams," respectively, as compared to rating as minor concerns in 0.07% and 0.01%, respectively. Other water quantity factors are rated as major and minor concerns in 1% or less of "all streams." "Perennial streams" follow the same pattern.

Sources Associated with Water Quantity Factors

Each respondent was requested to indicate the probable sources of water quantity factors adversely affecting the reaches selected in the Survey (Table 13 and Figure 9). The Survey results indicate that in

□   ALL STREAMS

■   PERENNIAL STREAMS

PARAMETER CODE

TOTAL LENGTH IN MILES

natural causes are the principal source associated with water quantity factors. Agricultural diversions are also a principal source. Natural conditions adversely affect the quantity of water in 50.1% of "all streams" and 25.7% of "perennial streams." Agricultural diversions have adverse effects in 13.6% of "all streams" and 11.0% of "perennial streams." All other sources each occur in less than 4% of "all streams."

The sources of water quantity problems in "perennial streams" occur in the same order of importance as in "all streams," but at a decreased magnitude. This is especially true for natural conditions, which occur in approximately one-half as many miles for "perennial streams" as for "all streams." Natural conditions, the largest overall contributor to the lack of water as fish habitat, is rated as a major concern in 37.7% and a minor concern in 12.4% of "all stream" miles. Agricultural diversions are major concerns in 8.2% of "all stream" miles and minor concerns in 5.4%.

Usable Habitat Factors

Each respondent was requested to indicate whether habitat was limiting the use of the reach by the fish community (Table 14 and Figure 10). Odum (1971) states that: "The habitat of an organism is the place where it lives or the place where one would go to find it. Habitat may also refer to the place occupied by an entire community."

Four principal habitat factors were found to adversely affect the fish community: overall adult/juvenile habitat (40.4% of "all streams"), overall egg/larvae habitat (28.3% of "all streams"), specific habitat-pools (20.7% of "all streams"), and specific habitat-gravel substrate (16.4% of "all streams"). Pools or fish resting areas are generally thought of as adult/juvenile habitat. Gravel substrate is a necessary component for successful spawning of most stream fishes.

Overhead cover (e.g., trees over the water) and riffles (i.e., shallow rapids) are protective and food producing components of the aquatic system. Overhead cover is inadequate in 14.1% of "all streams" and riffles are inadequate in 13.5% of "all streams." The lack of these habitat components can add to predation, high water temperatures, and decreased food availability (Hynes 1970).

Results for "perennial streams" parallel those for "all streams," except for the magnitude of each limiting factor. In all cases, the limitations of these characteristics affected a smaller length and percentage of "perennial stream" miles than "all streams" miles.

Inadequate adult and juvenile habitat is ranked as a major concern in 22.7% and as a minor concern in 16.3% of "all stream" miles. Inadequate egg and larvae habitat follows a similar pattern, ranking as a major concern in 15.5% and as a minor concern in 11.3% of "all stream" miles. Lack of pools and gravel substrate have similar results. All other limiting habitat factors are equally divided between major and minor concerns. Results for "perennial streams" parallel those for "all streams."

35

[a] Additional statistics are in Appendix D, Tables D-16a and b.
[b] These additional categories were developed from clarification by the respondents under the "Other" category.
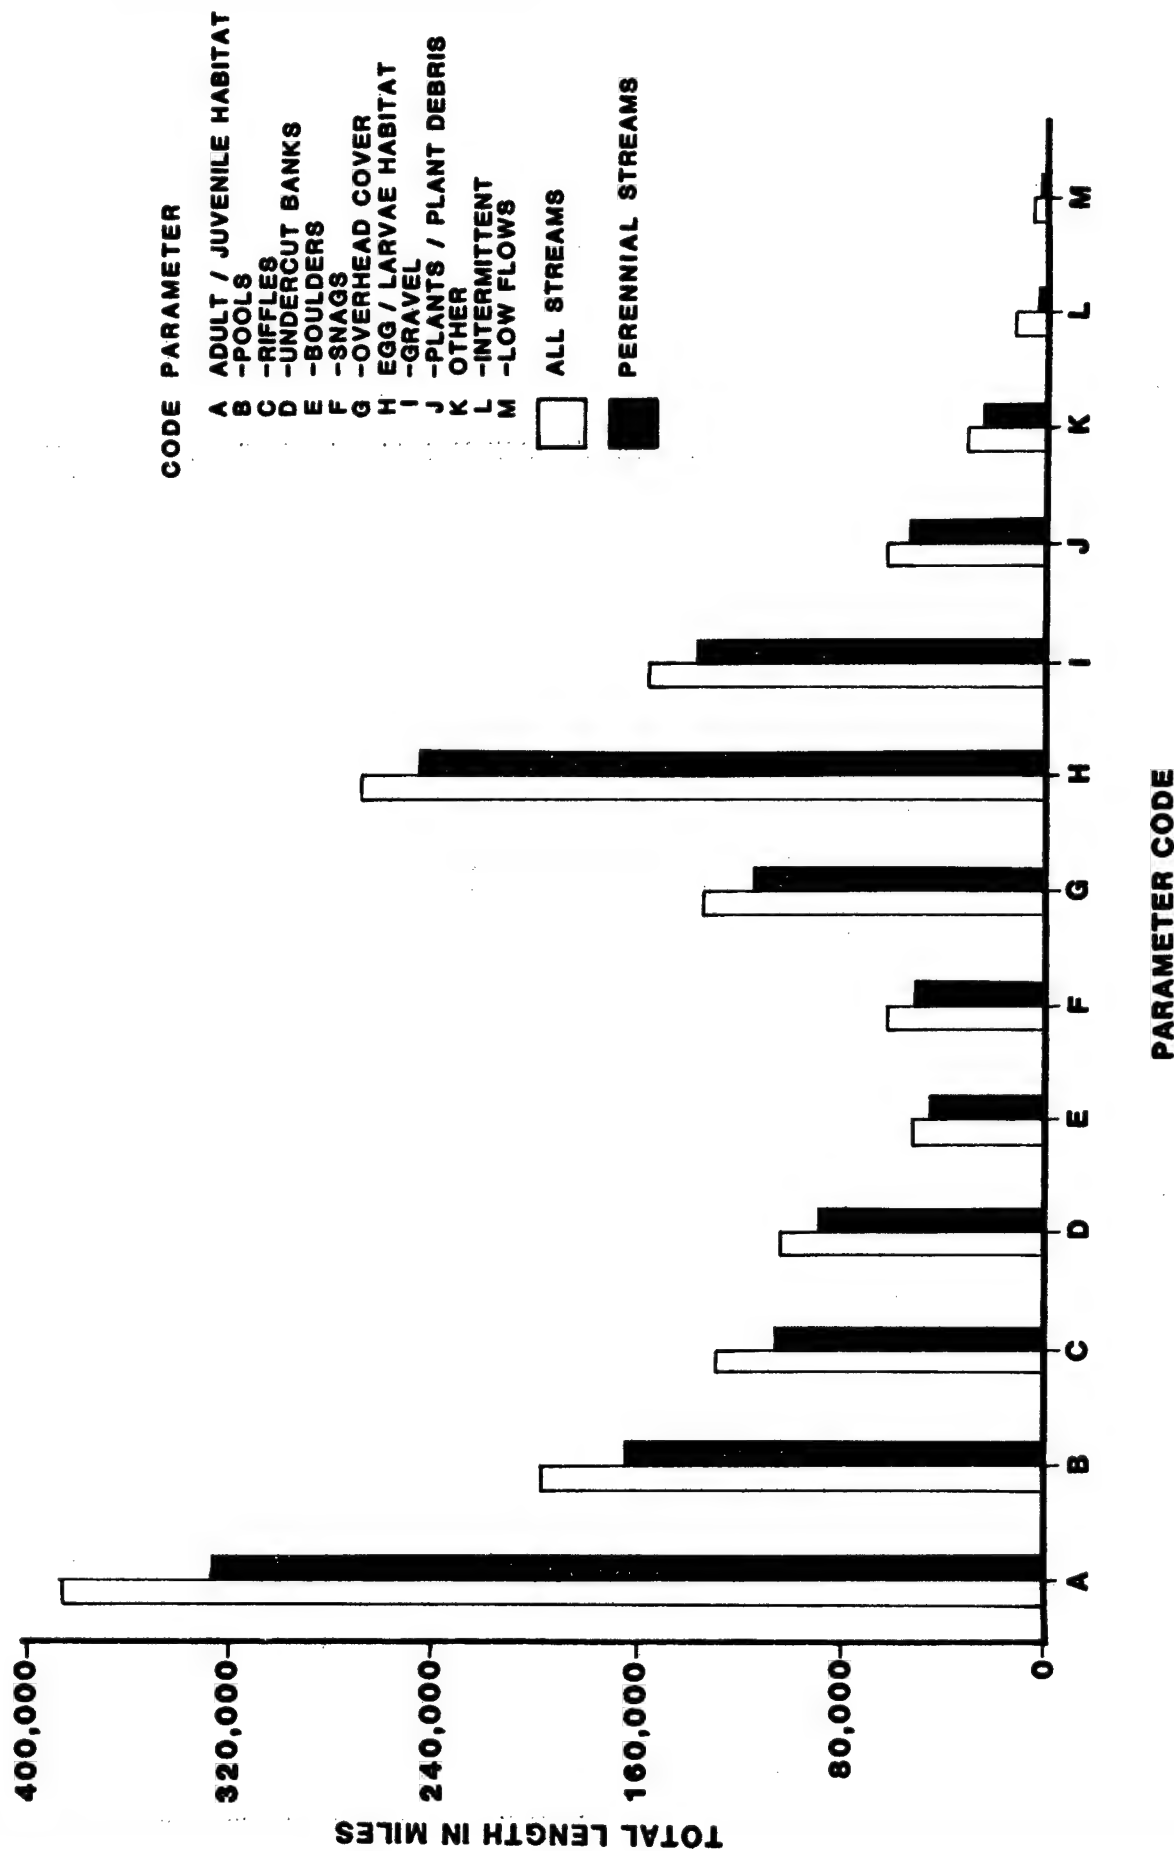

Figure 10. Usable habitat factors adversely affecting fish communities in the Nation's waters.

37

Sources Associated with Usable Habitat Factors

Respondents were requested to provide information on the probable sources of factors affecting usable habitat within the Nation's waters. Information on the probable sources of usable habitat problems can provide insight into methods to minimize and correct these problems. The Survey results are presented in Table 15 and Figure 11. Excessive siltation occurs in 27.9% of "all streams" and 24.8% of "perennial streams." Bank erosion and sloughing occur in 18.1% of "all streams" and 16.0% of "perennial streams." Natural causes occur in 17.6% of "all streams" and 13.4% of "perennial streams." Channelization occurs in 11.6% of "all streams" and 10.3% of "perennial streams." All other factors limiting usable habitat, such as channel modifications other than channelization and migration blockages, each occur in less than 5.0% of "all streams" and "perennial streams."

Excessive siltation is ranked as a major concern in 17.9% and a minor concern in 9.9% of "all streams." Bank erosion and sloughing are ranked approximately equally as a major concern (10.0%) and as a minor concern (8.2%) in "all streams." Natural causes are a major concern in 10.6% of "all streams," and a minor concern in 6.8%. Channelization is a major concern in 7.8% of "all streams" versus a minor concern in 3.8%. Other channel modifications and all other sources are generally ranked as minor concerns. Data for "perennial streams" follow the same pattern as for "all streams."

Fish Community Factors

The respondents were requested to indicate whether problems within the fish community were limiting fishery potential (Table 16 and Figure 12). Fish kills and contamination of fish flesh are the most prevalent factors, with fish kills affecting 15.3% and contamination of fish flesh affecting 9.4% of "all streams." All other factors, such as diseases, parasites, overharvest, and poaching, are each estimated to occur in less than 4.0% of "all streams."

Data for "perennial streams" indicate that fish kills and contamination of fish flesh occur in 12.1% and 8.6% of these streams, respectively. All other factors occur in less than 4.0% of all "perennial stream" miles.

The degree of concern expressed by the respondents about each of these limiting features suggests that these fish community problems are not significant on a National basis. Fish kills are more often considered a minor problem (8.4%) than a major one (6.9%) in "all streams." Contamination also follows this pattern. All other factors are considered minor problems in "all streams." Results for "perennial streams" are similar to those for "all streams" for all limiting factors.

Sources Associated with Fish Community Factors

Each respondent was requested to indicate the probable sources of limiting factors occurring in the fish community (Table 17 and Figure 13). Three sources were found to contribute the most to the problem: natural causes, pesticides, and other noxious or toxic substances.

Table 15. Sources of factors adversely affecting the Nation's fishery habitat[a].

[b] These additional categories were developed from clarification by the
respondents under the "Other" category.
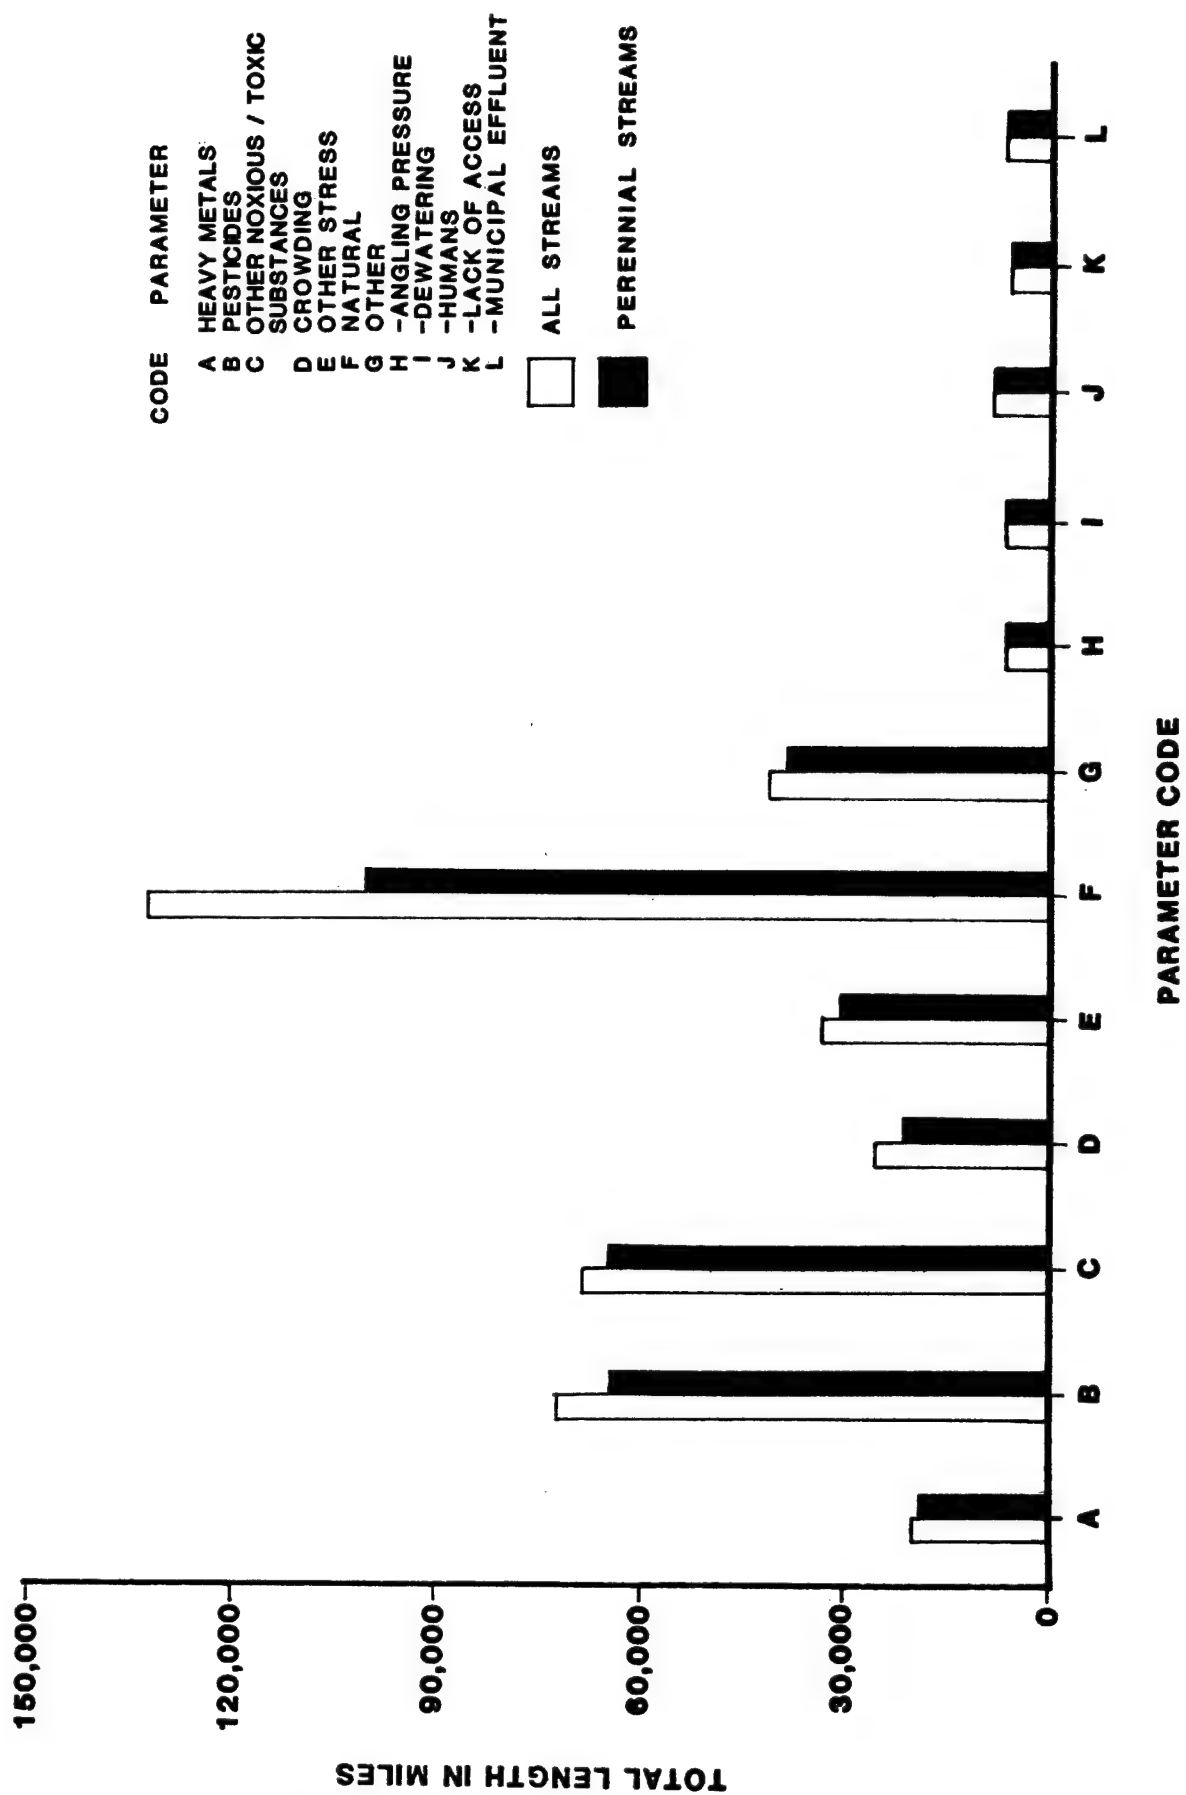

Figure 13. Probable sources of limiting factors adversely affecting fish communities in the Nation's waters.

44

The results for "all streams" show that natural causes (e.g., low flows that cause water temperatures to rise above lethal limits) occur in almost twice as many miles (13.8%) as the next ranked source, pesticides. Pesticides are a probable source in 7.6% of the Nation's waters. Other noxious or toxic substances are limiting in 7.2% of the Nation's waters.

Natural causes are the greatest source of limiting factors in fish communities in "perennial streams," occurring in 10.3%, followed by pesticides and other noxious or toxic substances. This is similar to the "all streams" analysis. All other sources occur with the same general distribution as in "all streams."

Natural causes are considered a major concern in 9.7% and a minor concern in 4.1% of "all streams." Pesticides and other noxious or toxic substances are fairly evenly split between being considered a major and a minor concern. Data for "perennial streams" follow the same pattern.

STATUS OF THE NATION'S WATERS AS REFLECTED BY THE FISH COMMUNITIES

Respondents ranked the status of each reach with respect to its ability to support fish, particularly sport fish and species of special concern. The rankings were from 0 to 5, with 0 defined as no ability to support any fish population and 5 defined as the maximum ability to support populations of sport fish and species of special concern. The ranks from 1 to 4 represented intermediate positions. This ranking was made after the respondents had considered all potential limiting factors, and their possible sources, affecting the ability of the stream to support fish. Respondents ranked the current condition of the reach (Question 5) and the condition 5 years ago (Question 6). They were then asked to speculate on the condition 5 years in the future if present trends in the reach continued (Question 7), and the likely condition 5 years in the future if the man-caused limiting factors were controlled or eliminated (Question 8).

Question 5 - Present Status of the Nation's Waters as Reflected by the Fish Communities

Each respondent was requested to rank the current condition of each reach using the evaluation criteria previously described. Results of the analysis of the current condition of each reach are presented in Table 18. For the category "all streams," 23.1% of the streams have a 0 ranking. This compares with 3.1% of "perennial streams." Ten percent of "all streams" are ranked as 1 (ability to support a nonsport fish population only), compared to 5.2% of "perennial streams." An estimated 21% of "all streams" are ranked as 2 (minimally able to support sport fish populations, species of special concern, or both); 17.2% of the "perennial streams" are ranked 2. Forty-six percent of "all streams" are ranked as a 3, 4, or 5 compared to 44% of "perennial streams." A small percentage of streams (3.9% of both "all streams" and "perennial streams") are able to support sport fish, species of special concern, or both at a maximum level (rank 5). The major differences between the "all streams" and "perennial streams" categories are the percentage of streams with no ability to support fish (rank 0) and streams with the ability to support only nonsport species of fish (rank 1).

45

Table 18. Current condition of the Nation's waters related to their ability to support fish[a].

Current Condition	Stream Length (miles)	Percentage
All Streams		
0	221,029	23.1
1	92,482	9.7
2	203,157	21.3
3	239,556	25.1
4	161,922	17.0
5	37,009	3.9
Perennial Streams		
0	29,872	3.1
1	49,311	5.2
2	166,306	17.3
3	228,660	23.9
4	156,239	16.4
5	36,130	3.8

[a]Additional comparison statistics are in Appendix D, Tables D-24a and b.

Question 6 - Past and Present Trends by Comparing Status of the Nation's Fish Communities.

Estimates were made to determine the ability of the Nation's waters to support fish communities 5 years ago (Table 19). Past condition was then compared with present conditions to determine changes in the ability of the Nation's waters to support fish populations (Figure 14). The diagonal line on the figure represents no change in rank. Above the diagonal line conditions have degraded during the past 5 years while below the diagonal line conditions have improved. For example, 15,000 stream miles have improved from a ranking of 2, 5 years ago, to a current ranking of 3. Overall, 91% of the streams kept the same rank, 4% have improved rank, and 5% have degraded rank.

Question 7 - Future Conditions if Present Trends in the Reach Continue

Respondents were asked to speculate on the condition of the reach in 5 years if present trends in the reach continue (Table 20). The results for both the "all stream" and "perennial stream" categories indicate that the respondents believe the ability of the Nation's waters to support sport fish species, species of special concern, or both, may decline in the next 5

Table 19. Past condition of the Nation's waters related to their ability to support fish.[a]

Past Condition	Stream Length (miles)	Percentage
All Streams		
0	216,853	22.7
1	91,757	9.6
2	207,999	21.8
3	239,121	25.0
4	160,348	16.8
5	39,078	4.1
Perennial Streams		
0	29,872	3.1
1	48,790	5.1
2	170,066	17.8
3	224,024	23.4
4	155,567	16.3
5	38,199	4.0

[a] See Appendix D, Tables D-24a and b for additional statistics.

years (Figure 15). In this figure, improvement is above the diagonal while degradation is below. For example, 41,000 miles of stream will degrade from an intermediate ability to support sport fish (rank 3) to a minimal ability to support sport fish (rank 2). Streams that will not support any fish will increase from 23.1% to 24.0% of "all streams" and from 3.1% to 3.5% of "perennial streams." Streams with a rank of 1 (only support non-sport fish species) will increase in "all streams" from 9.7% to 12.0%. In "perennial streams," rank 1 streams will increase from 5.2% to 7.4%. Streams with an intermediate ability to support fish (rank 3) will decline from 25.1% to 22.2% of "all streams" and 23.9% to 21.1% of "perennial streams."

Question 8 - Future Conditions with Controls on Man-Caused Limiting Factors

The Survey results indicate that in the view of the respondents there could be improvements in the Nation's waters over current and projected future conditions if man-caused limiting factors were controlled or eliminated (Table 20, previously presented). If the man-caused limiting factors affecting the fish communities are controlled, the number of streams ranked 0, 1, and 2 (those with minimal ability to support fish) would decrease, with a concomitant increase in the number of higher-ranked stream miles.

47

Figure 14. Comparison of current and past reach condition with respect to the ability of the reach to support sport fish.

Figure 15. Comparison of current and future reach condition with respect to the ability of the reach to support sport fish.

CURRENT CONDITION RANK
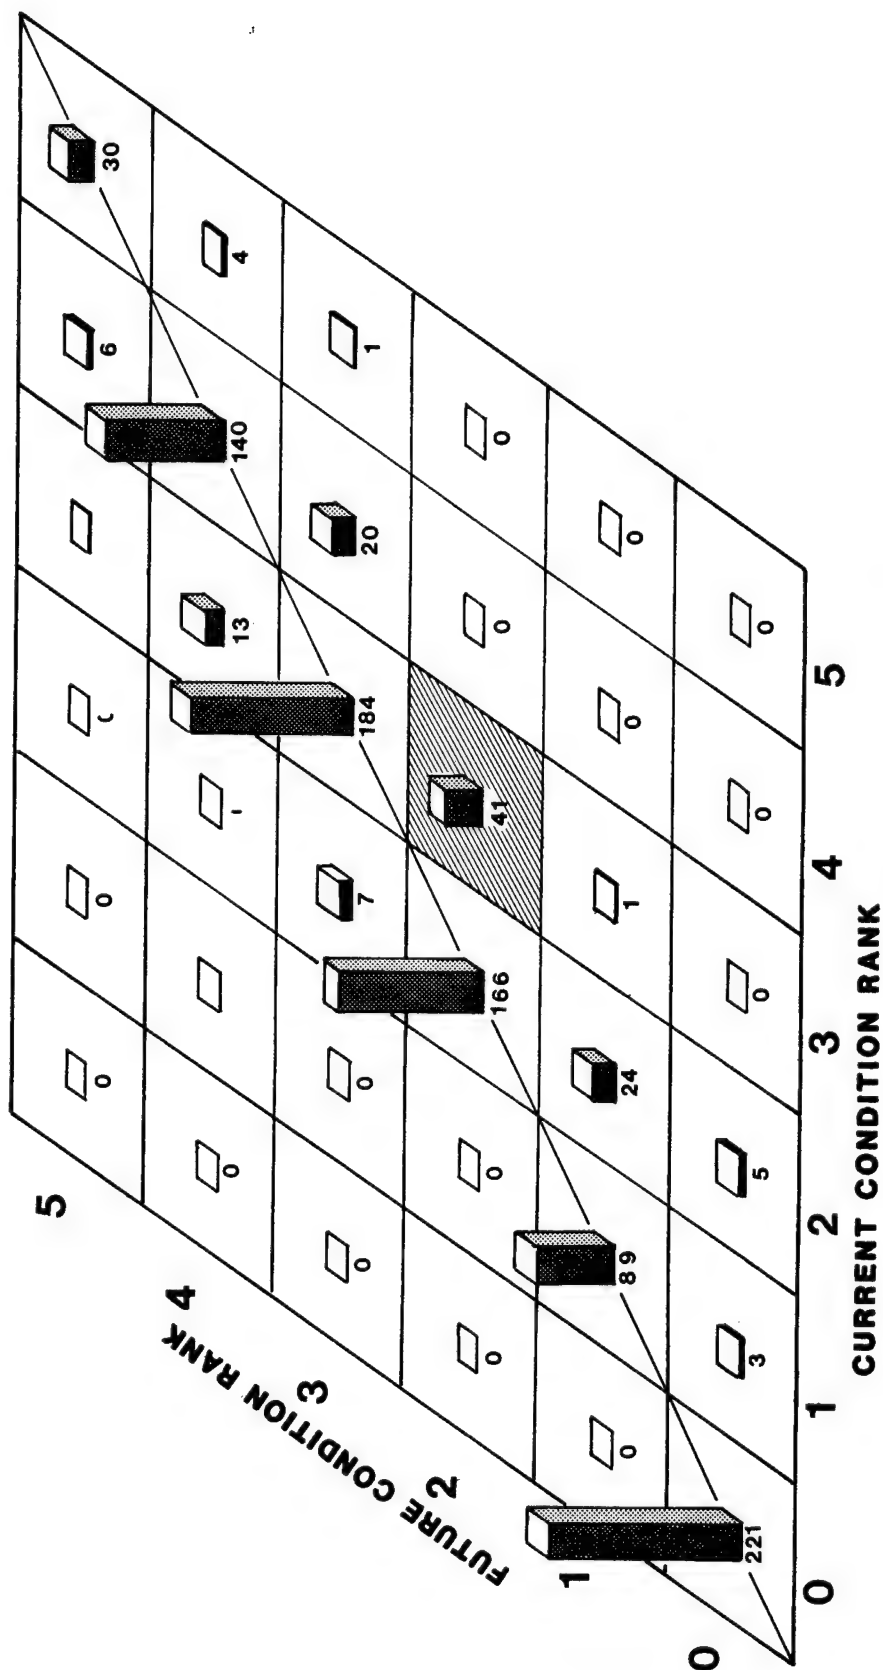

(All numbers are thousands of stream miles)

NOTE: IN READING THE GRAPH, THE DIAGONAL LINE REPRESENTS NO CHANGE IN STATUS. ABOVE THE DIAGONAL LINE INDICATES IMPROVEMENT, WHILE BELOW THE DIAGONAL LINE SHOWS DEGRADATION IN REACH CONDITIONS. FOR EXAMPLE, 41,000 MILES OF STREAM ARE PREDICTED TO DECREASE IN QUALITY FROM RANK 3 TO RANK 2 IN THE NEXT 5 YEARS IF CURRENT TRENDS CONTINUE.

FUTURE CONDITION RANK

50

CHAPTER 4. DISCUSSION

The National Fisheries Survey is significant in that it was the first
survey designed to relate the quality of the Nation's waters to the health
and viability of the biotic communities dependent on those water resources.
The fish community was selected as the best indicator of the biological
conditions of the Nation's waters for the following reasons:

> "Fish act as continuous monitors of water quality
> in contrast to standard sampling and testing
> programs which fail to identify brief episodes of
> polluted conditions. Fish generally have long
> life cycles, so that infrequent fish census may
> provide more information than more frequent counts
> of other organisms with shorter life cycles"
> (National Commission on Water Quality 1975).

The Survey design, the probability structure used to select the sample
reaches, the experience level of the respondents, and the high response rate
combined to provide reliable estimates of the status of the Nation's waters,
their ability to support fish communities, and informed judgment on limiting
factors affecting those fish communities.

The number and extent of data analysis were limited for this report by
available resources. Further analysis of the data could be conducted.
Recommendations for additional analyses are presented in Chapter 5.   The
following points highlight our initial interpretations of the data:

- ° Results of the Survey show that the two most prevalent sport fish
  species, largemouth bass and rainbow trout, respectively occur in
  27% and 22% of the Nation's waters. These species are representa-
  tive of warm-water and cold-water fish communities and are intoler-
  ant of poor water quality (Hynes 1970). Both species occupy the
  top of the aquatic food chain. Their wide distribution suggests
  that conditions in the majority of the Nation's waters are general-
  ly suitable for these two broad fish community types. At least one
  species of sport fish is present in 73% of the Nation's stream
  miles. Twenty-one percent of the Nation's total stream miles
  contain no fish. Many of these streams are intermittent or dry.

- ° Where nonsport fish occur, they are more abundant than sport fish.
  Three possible reasons exist for this greater abundance. First, the
  term nonsport fish encompasses a wide array of primary and inter-
  mediate level consumers that are used by sport fish as food.
  Primary consumers are expected to occur in greater numbers than
  secondary consumers (Odum 1971). Second, nonsport fish include

51

species that are tolerant of less than favorable habitat conditions and, therefore, may exhibit a wider distribution. For example, carp can breathe atmospheric oxygen in order to survive periods of low dissolved oxygen in the water. The third possibility is the Survey definition of sport fish as a fish species with a legal limit set by the State; many States consider some fish species without limits as sport fish.

o   The results of the Survey indicate that important components of fish habitat are limiting in almost half of the total stream miles. This condition has implications regarding the ability of the Nation's waters to continue supporting viable fish populations. This must also be considered in the context that "any modification of inland waters which produces displacement of ecosystem structure or function is to be regarded as a degradation of ecological integrity" (Cairns 1978).

c   A large portion of the Nation's streams, approximately 46%, are rated fair in terms of their ability to support sport fish populations. About one-third of the Nation's streams fall into the poor category. Many of these latter streams are intermittent and have little potential for improvement. Whether or not these streams can be managed effectively to improve their fisheries depends entirely on the site-specific cause of the adverse factors. Agricultural nonpoint sources appear to influence water quality on more stream miles than any other category of sources. Continued management through increased implementation of erosion controls and agricultural best management practices may be the most effective method of improving stream habitat conditions. These efforts would also contribute to an overall improvement in the Nation's water quality.

o   Habitat problems and water quality factors appear to be related. Specifically, there appears to be a direct relationship between loss of adult, juvenile, larval, and egg habitat and excessive siltation and bank erosion. Whether these sources are natural or man-caused was not determined in the Survey. However, Survey responses on water quality indicate that turbidity problems are largely associated with natural and agricultural sources. This is consistent with the Council on Environmental Quality's (CEQ's) Report, Environmental Quality (1981), which states that 50% of the Nation's water quality problems are a function of nonpoint source runoff and that the single largest cause of these problems is agricultural practices.

o   The status of the Nation's fisheries has not changed appreciably during the last 5 years. This is consistent with the CEQ's determination that water quality was maintained at a stable level during the 5 years preceding 1981, even though population and other growth pressures increased (Council on Environmental Quality 1981). The CEQ also concluded that evidence of improvement in water quality would not be immediate. The States, through their biennial reports to Congress, agree with this conclusion.

52

° In 1975, the National Commission on Water Quality estimated the percentage of areas suitable for sport fish populations without exercising best available technologies for eliminating pollution in the Nation's streams. In the 5 regions they examined, the range varied from 20% (Midwest Region) to 90% (Gulf of Alaska). The average National percentage of areas suitable for sport fish populations was 56.3%. The Commission projected that, by 1983, best available technology practices could raise this average percentage figure to 70.6%. If all discharges were eliminated, the average percentage was projected to be 72.6%. These percentages are similar to the National Fisheries Survey estimation that 67% of the Nation's stream miles have at least a minimal ability to support sport fish communities.

° The State fishery biologists responding to this Survey speculate that without control of man-caused sources of limiting factors, a dramatic decrease in the Nation's fish communities could occur in streams whose present capabilities are marginal (rank 3). Higher ranked streams would also be expected to decline in numbers. A commensurate increase in the number of streams that cannot support fish and in streams with a minimal ability to support sport fish would be expected.

° Because management of naturally-caused adverse conditions may be limited, management of man-caused adverse conditions appears to be the key to maintaining, and possibly improving, the status of the Nation's fish communities. The State fishery biologists responding to the Survey speculate that the capability of the Nation's waters to support sport fish could be greatly increased over present conditions if man-caused limiting factors were controlled.

The cooperation of the FWS, the EPA, and the States in the conduct of this project is in the spirit of recommendations by the CEQ Intraagency Task Force. The Task Force was formed in 1977 to assess needs in environmental data and monitoring programs (Council on Environmental Quality 1981). The level of cooperation in this project is a foundation upon which other agencies that are responsible for water quality and fishery quality can build to enhance the overall value and economy of Federal biological monitoring. The overall objective of the Survey was the development of estimates of the biological quality of the Nation's waters, as mandated by the Clean Water Act. This objective has been successfully met.

CHAPTER 5.   RECOMMENDATIONS FOR ADDITIONAL ANALYSES

This Survey is the first step in a continuing effort to increase our knowledge of the status of the Nation's waters, including their physical, chemical, and, especially, biological quality. The recommendations presented in this chapter describe several additional statistical analyses that could be performed on the existing Survey data. These analyses would enable a more definitive assessment of the relationships among limiting factors and sources that would further assist in interpretation of the results and formulation of conclusions. Additional analyses would benefit both fishery and water quality managers and planners as they attempt to allocate decreasing resources to areas of greatest need and greatest potential return.

DETERMINATION OF ASSOCIATIONS AMONG FACTORS AND CAUSES

The major area recommended for further analysis is the relationship among factors that adversely affect the Nation's waters and their sources. These analyses would identify direct relationships among the factors and sources. Statistical cross tabulations are especially recommended for the "major" factors and "major" sources defined by this report. These "major" factors and sources are those which occur in the most stream miles. Of special interest are the factors associated with point and nonpoint sources of pollution, especially those related to agricultural practices. These additional analyses would provide a basis for examining potential management options for both fish communities and water quality.

COMPARISON OF FACTORS AND CAUSES WITH A STREAM'S ABILITY TO SUPPORT FISH

The determination of associations among factors and causes could be compared with the stream rankings in terms of their ability to support fish communities. While this report draws some general inferences about the past, present, and predicted future status of the Nation's fisheries, it was unable to demonstrate specific adverse factors affecting the Nation's waters and sources associated with these estimates. With the ability to derive fairly good estimates of factors adversely affecting the Nation's waters and the sources of these factors, fish management programs, such as stocking, could be analyzed in terms of the percentage of rank 2 through rank 5 streams that are threatened with agricultural nonpoint sources of pollution and are also maintained by stocking. Other analyses, similar to this example, should also be conducted.

COMPARISON OF RESULTS WITH DESIGNATED USE CLASSIFICATIONS

The results of the comparison of factors, causes, and the ability of a stream to support fish populations could also be compared with designated

stream uses set by individual States. These designated uses, such as drinking water supply, industrial water supply, and fishery protection, are the uses set by the State's water quality standards. The results of this analysis could provide more insight into how well the Nation's water quality goals (i.e., fishable, swimmable) are being met. Reach conditions 5 years in the future, with and without control of man-caused factors, could be analyzed to further determine trends in the Nation's waters with respect to the attainment of designated use. The analysis would provide an estimate of whether the goals are attainable. The results would provide Federal, State, and local water quality management decisionmakers and planners with better information on the efficacy of existing regulations and the need for revisions.

GEOGRAPHICAL AND REGIONAL DIFFERENCES

Data on the geographical and regional differences in limiting factors, causes, and the past, present, and future status of the Nation's waters could be analyzed to provide additional clarification of problems and potential management strategies within known geographical boundaries. Boundaries could include ecoregion, major river basins, or other appropriate geographical divisions.

These analyses would provide needed data for consideration in planning priorities and allocation of resources. Specifically, these analyses could be used in the development of FWS Regional Resource Plans. Consistent use of the Survey sample design in each region, with expansion of the number of reaches sampled, could provide one of the first integrated assessments of regionally significant problems facing the Nation's water quality and fisheries resources. An expansion of the number of reaches sampled would be required because the existing sample data contain too few sampling points to have much ability to discover even important, large differences.

COMPARISON OF RESULTS WITH OTHER NATIONAL SURVEYS

The results of the Survey could be compared to the results of other National surveys such as the FWS National Survey of Fishing, Hunting, and Wildlife - Associated Recreation (U.S. Fish and Wildlife Service and U.S. Bureau of the Census 1982). Comparisons could include the public demand for quality fishing versus the ability to supply the demand. Economic evaluations relating potential losses in revenue to a wide variety of economic sectors as a result of not meeting the demand for quality fishing could also be conducted. Cost-benefit analyses of controlling significant factors adversely affecting stream fishery resources in areas of high public demand for quality fishing, e.g., urban areas, could also be investigated. These types of analyses would probably require an expansion of the existing Survey data base to take into account regional differences.

INTRODUCTION

This questionnaire is part of a combined U.S. Fish and Wildlife Service (FWS) and U.S. Environmental Protection Agency (EPA) effort to understand better the biological conditions of the nation's waters and to initiate the first nationwide fisheries data base. You have been selected to participate in the study because of your knowledge and expertise in the field of fisheries biology especially for the reach identified in this questionnaire.

The reach highlighted on the map was randomly selected from a national list of reaches contained in the EPA River Reach File. This file will also serve as the framework for the FWS fisheries data base.

The questions asked of you in this questionnaire were developed jointly by the FWS and the EPA, and were finalized based upon a pretest of the questionnaire conducted in the Fall of 1981. The principal focus of the questionnaire is on sport fish; this is not because sport fish are the only contributors to the value of the reach, but because the majority of available fisheries information concerns these species, and their presence or absence generally indicates conditions of prevailing water quality.

Because only a small number of reaches has been selected for this study, the participation of each scientist selected is extremely important. Please answer all questions. The information that you provide will be used only for statistical analysis of fisheries at the national level. You and your agency will receive copies of the final report of this National Fisheries Survey.

Appendix A. (Continued.)

For question 1, please print in the left hand column the scientific names of all species that occur in the reach at any time. Use additional names (e.g., *salmo gairdneri* – steelhead) if necessary to identify exactly the species present. Check or code all columns of the matrix that are applicable to these species. You may base your answer on personal experience through field sampling, discussion with colleagues or professional judgment.

For the purpose of answering this question, the following definitions apply:

- Sport fish: any fish with a legal limit (numbers, weight, or volume) set by your state's fishing regulations.

- Special concern: any fish species that is of particular concern to the state for preservation and management; included are state-listed threatened or endangered species, native species receiving special management attention, and other species of special concern for study and management; excluded are species receiving special management strictly to improve or diversify recreational fishing.

- Federal threatened or endangered species should be so indicated in the columns provided.

1.

POPULATION CODES

A – Presence
- A = Abundant
- C = Common
- U = Uncommon
- R = Rare
- E = Expected
- X = Unknown

B – Percentage of Reach with Species
- 1, 10, 20, etc.

C – Lifestage stocked
(if not stocked, leave blank)
- E = Egg
- L = Larvae
- F = Fingerling
- S = Subcatchable
- C = Catchable

D – Frequency of stocking
- 1 = Less than once annually
- 2 = Annually
- 3 = More than once annually

List the genus/species/subspecies, race, etc., for all fish species.

	Check all that apply to the species.													Refer to population codes in box at left.			
	Fish Classes							**Reach Description or Use**						**Population** A B C D

Appendix A. (Continued.)

Question 2 is concerned with the type of information you have available to complete this questionnaire. For the purpose of completing these questions, the following definitions apply:

- Qualitative sampling: this includes visual reconnaissance surveys and techniques which indicate only a species' presence or absence.

- Quantitative sampling: this includes techniques which produce numerical data in the form of population and productivity estimates, relative abundance ratings, biomass estimates, nest or redd counts, etc.

2. Has fish sampling occurred within this reach? CIRCLE ONE NUMBER

    Yes, definitely.......... 1 ⎤
    Yes, suspected........... 2 ⎦→ ANSWER A

    Doubtful................ 3 ⎤
    No, definitely........... 4 ⎥→ ANSWER B
    Unknown .... 5 ⎦

IF SAMPLING OCCURRED (YES, DEFINITELY OR SUSPECTED)

A. List the year(s) of sampling for each type of survey within this reach.

   Qualitative _____

   Quantitative _____

IF REACH WAS NOT SAMPLED (NO, DEFINITELY OR DOUBTFUL)

B. Has fish sampling occurred within the cataloging unit? CIRCLE ONE NUMBER

    Yes, definitely.......... 1 ⎤
    Yes, suspected........... 2 ⎦→ ANSWER C

    Doubtful................ 3 ⎤
    No, definitely........... 4 ⎥→ GO TO Q. 3
    Unknown .... 5 ⎦

IF SAMPLING OCCURRED (YES, DEFINITELY OR SUSPECTED)

C. List the year(s) of sampling for each type of survey within this cataloging unit.

   Qualitative _____

   Quantitative _____

3. Check the months the reach has water usable as fish habitat during a normal water year.

   All
   year J F M A M J J A S O N D None
   ☐   ☐ ☐ ☐ ☐ ☐ ☐ ☐ ☐ ☐ ☐ ☐ ☐ ☐

60

Question 4 concerns adverse conditions that may be affecting fish in the reach. Note that natural conditions are included in the tables. The tables should be completed one at a time. For example, if a reach is dammed and several adverse conditions result, each table (water quality, water quantity, usable habitat, fish community) should be completed as a unit. If the dam is causing gas supersaturation in the reach, #6 and #46 should be checked; if the dam blocks fish access to spawning gravel upstream, #27 and #71 should be checked. Check "other" only when necessary to explain reach conditions; keep explanations brief.

4. Is the survival, productivity, or use of the fish community being adversely affected by natural or man-made conditions in the reach? CIRCLE ONE NUMBER

Yes, definitely........... 1 ⎤
Yes, suspected.......... 2 ⎦ → ANSWER A

Doubtful............... 3 ⎤
No, definitely........... 4 ├→ GO TO Q. 5
Unknown.............. 5 ⎦

IF YES (DEFINITELY OR SUSPECTED):

A. Please complete the following tables by checking appropriate factors and sources. If possible, indicate if the factors and sources are of major or minor concern.

TABLE I.

WATER QUALITY

Check all applicable categories and circle 1 (Major) or 2 (Minor) in each category checked.

A. LIMITING FACTOR

	Major	Minor
1___Temperature too high	1	2
2___Temperature too low	1	2
3___Turbidity	1	2
4___Salinity	1	2
5___Dissolved oxygen	1	2
6___Gas supersaturation	1	2
7___pH too acidic	1	2
8___pH too basic	1	2
9___Nutrient deficiency	1	2
10___Nutrient surplus	1	2
11___Toxic substances	1	2

_____	1	2

H. PROBABLE SOURCE

	Major	Minor
75___Heavy metals	1	2
76___Pesticides	1	2
77___Other noxious/toxic substances	1	2
78___Crowding	1	2
79___Other stress	1	2
80___Natural	1	2
81___Unknown	1	2
82___Other (specify below)		
_____	1	2

The next few questions are a subjective but necessary part of this survey. To provide some standardization for response, a "ladder" is shown below describing the spectrum of conditions that could exist in an aquatic ecosystem in terms of the fish community. At the top of the ladder is the ideal situation of maximum ability to support a fish community of high interest, i.e., a community of sport fish or other species of special concern. The bottom of the ladder represents a reach that is incapable of supporting any fish community. Please use this ladder as a reference in answering questions 5, 6, 7, 8, and 9.

```
  5
  4
  3
  2
  1
  0
```

The reach exhibits a maximum ability to support a community of sport fish, species of special concern, or both.

The reach exhibits a minimum ability to support a community of sport fish, species of special concern, or both.

The reach exhibits an ability to support a nonsport fish population only.

The reach has no ability to support any fish population.

CHECK ONE BOX FOR EACH QUESTION

5. Using the scale shown on the opposite page, how would you rank the current conditions of the reach?

    ☐   ☐   ☐   ☐   ☐   ☐
    0   1   2   3   4   5

6. Again using this scale, how would you rank the conditions of the reach five years ago?

    ☐   ☐   ☐   ☐   ☐   ☐
    0   1   2   3   4   5

7. If present trends in the reach continue, how will it rank five years from now?

    ☐   ☐   ☐   ☐   ☐   ☐
    0   1   2   3   4   5

8. Should the man-caused limiting factors (if previously indicated in question 4A) be eliminated or controlled, how will the reach rank five years from now?

    ☐   ☐   ☐   ☐   ☐   ☐
    0   1   2   3   4   5

9. Considering, as a standard, a reach in the same or adjacent cataloging unit with the greatest ability to support sport fish, how would you rate <u>that</u> reach on the scale?

    ☐   ☐   ☐   ☐   ☐   ☐
    0   1   2   3   4   5

USE THIS PAGE ONLY IF YOU NEED TO LIST MORE THAN 11 SPECIES OF FISH IN QUESTION 1.

POPULATION CODES

A — Presence

- A = Abundant
- C = Common
- U = Uncommon
- R = Rare
- E = Expected
- X = Unknown

B — Percentage of Reach with Species

1, 10, 20, etc.

C — Lifestage stocked
(if not stocked, leave blank)

- E = Egg
- L = Larvae
- F = Fingerling
- S = Subcatchable
- C = Catchable

D — Frequency of stocking

- 1 = Less than once annually
- 2 = Annually
- 3 = More than once annually

List the genus/species/subspecies, race, etc., for all fish species.

Check all that apply to the species.

Refer to population codes in box at left.

Box 7921
Madison, Wisconsin 53707

Mr. John Baughman
Fisheries Management Coordinator
Wyoming Game & fish Dept.
Cheyenne, Wyoming 82002

APPENDIX C. NATIONAL FISHERIES SURVEY LISTING OF FISH SPECIES

SCIENTIFIC NAME	COMMON NAME
ACANTHARCHUS POMOTIS	MUD SUNFISH
ACIPENSER FULVESCENS	LAKE STURGEON
ACIPENSER OXYRHYNCHUS	ATLANTIC STURGEON
ACROCHEILUS ALUTACEUS	CHISELMOUTH
ALOSA AESTIVALIS	BLUEBACK HERRING
ALOSA CHRYSOCHLORIS	SKIPJACK HERRING
ALOSA MEDIOCRIS	HICKORY SHAD
ALOSA PSEUDOHARENGUS	ALEWIFE
ALOSA SAPIDISSIMA	AMERICAN SHAD
AMBLOPLITES ARIOMMUS	SHADOW BASS
AMBLOPLITES CONSTELLATUS	OZARK BASS
AMBLOPLITES RUPESTRIS	ROCK BASS
AMIA CALVA	BOWFIN
AMMOCRYPTA ASPRELLA	CRYSTAL DARTER
AMMOCRYPTA BEANI	NAKED SAND DARTER
AMMOCRYPTA MERIDIANA	SOUTHERN SAND DARTER
AMMOCRYPTA VIVAX	SCALY SAND DARTER
AMPHISTICHUS RHODOTERUS	REDTAIL SURFPERCH
ANCHOA MITCHILLI	BAY ANCHOVY
ANGUILLA ROSTRATA	AMERICAN EEL
APHREDODERUS SAYANUS	PIRATE PERCH
APLODINOTUS GRUNNIENS	FRESHWATER DRUM
ARCHOSARGUS PROBATOCEPHALUS	SHEEPSHEAD
ARIUS FELIS	HARDHEAD CATFISH
BAGRE MARINUS	GAFFTOPSAIL CATFISH
BAIRDIELLA CHRYSOURA	SILVER PERCH
BREVOORTIA GUNTERI	FINESCALE MENHADEN
BREVOORTIA TYRANNUS	ATLANTIC MENHADEN
CAMPOSTOMA ANOMALUM	CENTRAL STONEROLLER
CAMPOSTOMA OLIGOLEPIS	LARGESCALE STONEROLLER
CARASSIUS AURATUS	GOLDFISH
CARPIODES CARPIO	RIVER CARPSUCKER
CARPIODES CYPRINUS	QUILLBACK
CARPIODES SP.	CARPSUCKERS
CARPIODES VELIFER	HIGHFIN CARPSUCKER
CATOSTOMUS CATOSTOMUS	LONGNOSE SUCKER
CATOSTOMUS COLUMBIANUS	BRIDGELIP SUCKER
CATOSTOMUS COMMERSONI	WHITE SUCKER
CATOSTOMUS DISCOBOLUS	BLUEHEAD SUCKER
CATOSTOMUS LATIPINNIS	FLANNELMOUTH SUCKER
CATOSTOMUS MACROCHEILUS	LARGESCALE SUCKER
CATOSTOMA MICROPS	MODOC SUCKER
CATOSTOMUS PLEBEIUS	RIO GRANDE SUCKER
CATOSTOMUS SP.	SUCKERS
CATOSTOMUS SYNCHEILUS	FINE-SCALED SUCKER
CATOSTOMUS TAHOENSIS	TAHOE SUCKER
CENTRARCHUS MACROPTERUS	FLIER
CENTROPOMUS SP.	SNOOK

CHOLOGASTER CORNUTA	SWAMPFISH
CLARIAS BATRACHUS	WALKING CATFISH
CLINOSTOMUS ELONGATUS	REDSIDE DACE
CLINOSTOMUS FUNDULOIDES	ROSYSIDE DACE
CLUPEA HARENGUS HARENGUS	ATLANTIC HERRING
COREGONUS CLUPEAFORMIS	LAKE WHITEFISH
COREGONUS SP.	CISCO
COTTUS ASPER	PRICKLY SCULPIN
COTTUS BAIRDI	MOTTLED SCULPIN
COTTUS CAROLINAE	BANDED SCULPIN
COTTUS COGNATUS	SLIMY SCULPIN
COTTUS CONFUSUS	SHORTHEAD SCULPIN
COTTUS GIRARDI	POTAMAC SCULPIN
COTTUS GULOSUS	RIFFLE SCULPIN
COTTUS RHOTHEUS	TORRENT SCULPIN
COTTUS SP.	SCULPINS
COUESIUS PLUMBEUS	LAKE CHUB
CTENOPHARYNGODON IDELLA	GRASS CARP
CULAEA INCONSTANS	BROOK STICKLEBACK
CYCLEPTUS ELONGATUS	BLUE SUCKER
CYPRINUS CARPIO	COMMON CARP
CYPRINODON RUBROFLUVIATILIS	RED RIVER PUPFISH
DORMITATOR MACULATUS	FAT SLEEPER
DOROSOMA CEPEDIANUM	GIZZARD SHAD
DOROSOMA PETENENSE	THREADFIN SHAD
DOROSOMA SP.	SHADS
ELASSOMA SP.	PYGMY SUNFISH
ELASSOMA ZONATUM	BANDED PYGMY SUNFISH
ELOPS SAURUS	LADYFISH
ENNEACANTHUS CHAETODUN	BLACKBANDED SUNFISH
ENNEACANTHUS GLORIOSUS	BLUESPOTTED SUNFISH
ENNEACANTHUS OBESUS	BANDED SUNFISH
ERICYMBA BUCCATA	SILVERJAW MINNOW
ERIMYZON OBLONGUS	CREEK CHUBSUCKER
ERIMYZON SP.	CHUBSUCKER
ERIMYZON SUCETTA	LAKE CHUBSUCKER
ERIMYZON TENUIS	SHARPFIN CHUBSUCKER
ESOX AMERICANUS AMERICANUS	PICKEREL
ESOX AMERICANUS VERMICULATUS	GRASS PICKEREL
ESOX LUCIUS	NORTHERN PIKE
ESOX MASQUINONG-LUCIUS(HY)	TIGER MUSKY (HYBRID)
ESOX MASQUINONGY	MUSKELLUNGE (MUSKY)
ESOX NIGER	CHAIN PICKEREL
ESOX SP.	PICKEREL
ETHEOSTOMA ASPRIGENE	MUD DARTER
ETHEOSTOMA BLENNIODES	GREENSIDE DARTER
ETHEOSTOMA CAERULEUM	RAINBOW DARTER
ETHEOSTOMA CHLOROBRANCHIUM	GREENFIN DARTER
ETHEOSTOMA CHLOROSOMUM	ASHY DARTER
ETHEOSTOMA COLLETTEI	CREOLE DARTER
ETHEOSTOMA EDWINI	CHERRY DARTER
ETHEOSTOMA FLABELLARE	FANTAIL DARTER

ETHEOSTOMA FRICKSIUM	SAVANNAH DARTER
ETHEOSTOMA FUSIFORME	SWAMP DARTER
ETHEOSTOMA GRACILE	SLOUGH DARTER
ETHEOSTOMA HISTRIO	HARLEQUIN DARTER
ETHEOSTOMA INSCRIPTUM	TURQUOISE DARTER
ETHEOSTOMA JORDANI	GREENBREAST DARTER
ETHEOSTOMA NIGRUM	JOHNNY DARTER
ETHEOSTOMA OBEYENSE	BARCHEEK DARTER
ETHEOSTOMA OLMSTEDI	TESSELLATED DARTER
ETHEOSTOMA PALIDIDORSUM	PALEBACK DARTER
ETHEOSTOMA PARVIPINNE	GOLDSTRIPE DARTER
ETHEOSTOMA PROLIARE	CYPRESS DARTER
ETHEOSTOMA PUNCTULATUM	STIPPLED DARTER
ETHEOSTOMA RADIOSUM	ORANGEBELLY DARTER
ETHEOSTOMA RUFILINEATUM	REDLINE DARTER
ETHEOSTOMA RUPESTRE	ROCK DARTER
ETHEOSTOMA SERRIFERUM	SAWCHEEK DARTER
ETHEOSTOMA SP.	DARTERS
ETHEOSTOMA SPECTABILE	ORANGETHROAT DARTER
ETHEOSTOMA STIGMAEUM	SPECKLED DARTER
ETHEOSTOMA SWAINI	GULF DARTER
ETHEOSTOMA ULOCENTRA	*UNDESCRIBED*
ETHEOSTOMA VARIATUM	VARIEGATED DARTER
ETHEOSTOMA VIRGATUM	STRIPED DARTER
ETHEOSTOMA VITREUM	GLASSY DARTER
ETHEOSTOMA WHIPPLEI	REDFIN DARTER
ETHEOSTOMA ZONALE	BANDED DARTER
EXOGLOSSUM MAXILLINGUA	CUTLIPS MINNOW
FUNDULUS CATENATUS	NORTHERN STUDFISH
FUNDULUS CHRYSOTUS	GOLDEN TOPMINNOW
FUNDULUS DIAPHANUS	BANDED KILLIFISH
FUNDULUS LINEOLATUS	LINED TOPMINNOW
FUNDULUS NOTATUS	BLACKSTRIPE TOPMINNOW
FUNDULUS NOTTI	STARHEAD TOPMINNOW
FUNDULUS OLIVACEUS	BLACKSPOTTED TOPMINNOW
FUNDULUS SP.	TOPMINNOW
FUNDULUS ZEBRINUS	PLAINS KILLIFISH
GAMBUSIA AFFINIS	MOSQUITOFISH
GASTEROSTEUS ACULEATUS	THREESPINE STICKLEBACK
GILA BICOLOR	TUI CHUB
GILA COPEI	LEATHERSIDE CHUB
GILA ROBUSTA	ROUNDTAILED CHUB
GOBIOMORUS DORMITOR	BIGMOUTH SLEEPER
HESPEROLEUCUS PARVIPINNIS	HYBRID
HIODON ALOSOIDES	GOLDEYE
HIODON TERGISUS	MOONEYE
HYBOPSIS AESTIVALIS	SPECKLED CHUB
HYBOPSIS AMBLOPS	BIGEYE CHUB
HYBOGNATHUS ARGYRITIS	WESTERN SILVERY MINNOW
HYBOPSIS DISSIMILIS	STREAMLINE CHUB
HYBOPSIS GELIDA	STURGEON CHUB
HYBOPSIS GRACILIS	FLATHEAD CHUB

HYBOGNATHUS HANKINSONI	BRASSY MINNOW
HYBOGNATHUS HAYI	CYPRESS MINNOW
HYBONATHUS HAYI	CYPRESS MINNOW
HYBOPSIS HYPSINOTUS	HIGHBACK CHUB
HYBOPSIS LABROSA	THICKLIP CHUB
HYBOGNATHUS NUCHALIS	MISSISSIPPI SILVERY CHUB
HYBOGNATHUS REGIUS	EASTERN SILVERY MINNOW
HYBOPSIS RUBRIFRONS	ROSYFACE CHUB
HYBOGNATHUS SP.	MINNOWS
HYBOPSIS SP.	CHUB
HYBOPSIS STORERIANA	SILVER CHUB
HYPENTELIUM ETOWANUM	ALABAMA HOG SUCKER
HYPENTELIUM NIGRICANS	NORTHERN HOG SUCKER
HYPOMESUS TRANSPACIFICUS	DELTA SMELT
ICHTHYOMYZON CASTANEUS	CHESTNUT LAMPREY
ICHTHYOMYZON GAGEI	SOUTHERN BROOK LAMPREY
ICHTHYOMYZON UNICUSPIS	SILVER LAMPREY
ICTALURUS CATUS	WHITE CATFISH
ICTALURUS FURCATUS	BLUE CATFISH
ICTALURUS MELAS	BLACK BULLHEAD
ICTALURUS NATALIS	YELLOW BULLHEAD
ICTALURUS NEBULOSUS	BROWN BULLHEAD
ICTALURUS PLATYCEPHALUS	FLAT BULLHEAD
ICTALURUS PUNCTATUS	CHANNEL CATFISH
ICTALURUS SERRACANTHUS	SPOTTED BULLHEAD
ICTALURUS SP.	CATFISH
ICTIOBUS BUBALUS	SMALLMOUTH BUFFALO
ICTIOBUS CYPRINELLUS	BIGMOUTH BUFFALO
ICTIOBUS NIGER	BLACK BUFFALO
ICTIOBUS SP.	BUFFALOS
LABIDESTHES SICCULUS	BROOK SILVERSIDE
LAMPETRA AEPYPTERA	LEAST BROOK LAMPREY
LAMPETRA APPENDIX	AMERICAN BROOK LAMPREY
LEIOSTOMUS XANTHURUS	SPOT
LEPISOSTEUS OCULATUS	SPOTTED GAR
LEPISOSTEUS OSSEUS	LONGNOSE GAR
LEPISOSTEUS PLATOSTOMUS	SHORTNOSE GAR
LEPISOSTEUS PLATYRHINCUS	FLORIDA GAR
LEPISTOSTEUS SPATULA	ALLIGATOR GAR
LEPOMIS AURITUS	REDBREAST SUNFISH
LEPOMIS CYANELLUS	GREEN SUNFISH
LEPOMIS GIBBOSUS	PUMPKINSEED
LEPOMIS GULOSUS	WARMOUTH
LEPOMIS HUMILUS	ORANGESPOTTED SUNFISH
LEPOMIS MACROCHIRUS	BLUEGILL
LEPOMIS MARGINATUS	DOLLAR SUNFISH
LEPOMIS MEGALOTIS	LONGEAR SUNFISH
LEPOMIS MICROLOPHUS	REDEAR SUNFISH
LEPOMIS PUNCTATUS	SPOTTED SUNFISH
LEPOMIS SP.	SUNFISH
LEPOMIS SYMMETRICUS	BANTAM SUNFISH
LOTA LOTA	BURBOT

LUCANIA PARVA	RAINWATER KILLIFISH
LUTJANUS GRISEUS	GRAY SNAPPER
MEGALOPS ATLANTICUS	TARPON
MENIDIA AUDENS	MISSISSIPPI SIVERSIDE
MENIDIA BERYLLINA	INLAND SILVERSIDE
MICROPTERUS COOSAE	REDEYE BASS
MICROPTERUS DOLOMIEUI	SMALLMOUTH BASS
MICROPTERUS PUNCTULATUS	SPOTTED BASS
MICROPTERUS SALMOINDES	LARGE MOUTH BASS
MICROPOGON UNDULATUS	ATLANTIC CROAKER
MINYTREMA MELANOPS	SPOTTED SUCKER
MORONE AMERICANA	WHITE PERCH
MORONE CHRYSOPS	WHITE BASS
MORONE MISSISSIPPIENSIS	YELLOW BASS
MORONE SAXATILUS	STRIPED BASS
MOXOSTOMA ANISURUM	SILVER REDHORSE
MOXOSTOMA CARINATUM	RIVER REDHORSE
MOXOSTOMA CONGESTUM	GRAY REDHORSE
MOXOSTOMA DUQUESNEI	BLACK REDHORSE
MOXOSTOMA ERYTHRURUM	GOLDEN REDHORSE
MOXOTOMA LACHNERI	GREATER JUMPROCK
MOXOSTOMA MACROLEPIDOTUM	SHORTHEAD REDHORSE
MOXOSTOMA POECILURUM	BLACKTAIL REDHORSE
MOXOTOMA ROBUSTUM	SMALLFIN REDHORSE
MOXOSTOMA RUPISCARTES	STRIPED JUMPROCK
MOXOSTOMA SP.	SUCKERS
MOXOSTOMA VALENCIENNESI	GREATER REDHORSE
MUGIL CEPHALUS	STRIPED MULLET
MYLOCHEILUS CAURINUS	PEAMOUTH
MYLOPHARODON CONOCEPHALUS	HARDHEAD
NOCOMIS BIGUTTATUS	HORNYHEAD CHUB
NOCOMIS LEPTOCEPHALUS	BLUE HEAD CHUB
NOCOMIS MICROPOGON	RIVER CHUB
NOTEMIGONUS CRYSOLEUCAS	GOLDEN SHINER

PERCOPSIS TRANSMONTANA	SAND ROLLER
PERCINA URANIDAE	STARGAZING DARTER
PETROMYZON MARINUS	SEA LAMPREY
PHENACOBIUS CATOSTOMUS	RIFFLE MINNOW
PHENACOBIUS MIRABILIS	SUCKERMOUTH MINNOW
PHOXINUS EOS	NORTHERN REDBELLY DACE
PHOXINUS ERYTHROGASTER	SOUTHERN REDBELLY DACE
PIMEPHALES NOTATUS	BLUNTNOSE MINNOW
PIMEPHALES PROMELAS	FATHEAD MINNOW
PIMEPHALES SP.	MINNOWS
PIMEPHALES VIGILAX	BULLHEAD MINNOW
POECILIA MEXICANA	SHORTFIN MOLLY
POGONIAS CROMIS	BLACKDRUM
POLYODON SPATHULA	PADDLEFISH
POMATOMUS SALTATRIX	BLUEFISH
POMOXIS ANNULARIS	WHITE CRAPPIE
POMOXIS NIGROMACULATUS	BLACK CRAPPIE
POMOXIS SP.	CRAPPIE

PROSOPIUM COULTERI	PYGMY WHITEFISH
PYLODICTUS OLIVARIS	FLATHEAD CATFISH
RHINICHTHYS ATRATULUS	BLACKNOSE DACE
RHINICHTHYS CATARACTAE	LONGNOSE DACE
RHINICHTHYS FALCATUS	LEOPARD DACE
RHINICHTHYS OSCULUS	SPECKLED DACE
RHINICHTHYS SP.	DACE
RICHARDSONIUS BALTEATUS	REDSIDE SHINER
RICHARDSONIUS EGREGIUS	LAHONTON REDSIDE
SALMO GAIRDNERI	RAINBOW (NOT ANADROMOUS)
SALMO SALAR	ATLANTIC SALMON
SALMO SALAR	ATLANTIC SALMON (LAND LOCKED)
SALMO TRUTTA	BROWN TROUT
SALVELINUS CONFLUENTUS	BULL TROUT
SCAPHIRHYNCHUS ALBUS	PALLID STURGEON
SCAPHIRHYNCHUS PLATORYNCHUS	SHOVELNOSE STURGEON
SCIAENOPS OCELLATUS	RED DRUM (CHANNEL BASS)
SEMOTILUS ATROMACULATUS	CREEK CHUB
SEMOTILUS CORPORALIS	FALLFISH
SEMOTILUS MARGARITA	PEARL DACE
SPIRINCHUS THALEICHTHYS	LONGFIN SMELT
STIZOSTEDION CANADENSE	SAUGER
STIZOSTEDION VITREUM VITREUM	WALLEYE
STRONGYLURA MARINA	ATLANTIC NEEDLEFISH
THALEICHTHYS PACIFICUS	EULACHON
TINCA TINCA	TENCH
TRINECTES MACULATUS	HOGCHOKER
UMBRA LIMI	CENTRAL MUDMINNOW
UMBRA PYGMAEA	EASTERN MUDDMINNOW
XIPHOPHORUS VARIATUS	VARIABLE PLATYFISH
XYRAUCHEN TEXANUS	RAZORBACK SUCKER

APPENDIX D. NATIONAL FISHERIES SURVEY SUPPLEMENTAL DATA

Table D-1a. Ten most prevalent sports fish species in the Nation's waters (all streams).

Common Name	Length (Miles)	Standard Error	Confidence Interval Unbiased (95%)	Biased	Percent
Largemouth bass	263859	20951	221957	305761	27.31
Rainbow trout steelhead	213461	24645	164171	262751	22.09
Bluegill	188495	21232	146031	230959	19.51
Channel catfish	148343	18647	111049	185637	15.35
Smallmouth bass	142142	16821	108500	175784	14.71
Green sunfish	126074	17616	90842	161306	13.05
Brook trout	103507	14811	73885	133129	10.71
Black crappie	98190	14777	68636	127744	10.16
Spotted bass	98129	16317	65495	130763	10.16
Rockbass	94682	16318	62046	127318	9.80

80

Table D-1b. Ten most prevalent nonsport fish species in the Nation's waters (all streams).

Common Name	Length (Miles)	Standard Error	Confidence Interval Unbiased (95%)	Biased	Percent
Common carp	187417	18303	150811	224023	19.4
Creek chub	176709	18221	140267	213151	18.29
White sucker	166823	19354	128115	205531	17.27
Gizzard shad	131730	17422	96886	166574	13.63
Bluntnose minnow	126665	20228	86209	167121	13.11
Stoneroller	122337	17370	87597	157077	12.66
Green sunfish	115234	19274	76686	153782	11.93
Common shiner	112112	16671	78770	145454	11.6
Fathead minnow	110531	16685	77161	143901	11.44
Golden shiner	106602	15996	74610	138594	11.03

81

Table D-2a. Distribution of fish types by class (all streams).

Fish Class	Length (Miles)	Standard Error	Confidence Interval (95%) Unbiased		Biased		Percent
Sport	701780	29806	642168	761392	502956	770104	72.64

Volume II is FWS/OBS-84/14; Volume III is FWS/OBS-84/07

16. Abstract (Limit: 200 words)

This report presents initial results of the National Fisheries Survey, an assessment of the biological condition of the Nation's waters conducted jointly by the U.S. Environmental Protection Agency (EPA) and the U. S. Fish and Wildlife Service (FWS) in 1982. Sport fish species, Federally-designated threatened and endangered fish species, and State-designated fish species of special concern were used as indicators of biological status. For the purposes of this Survey, the Nation's waters were defined as all flowing waters in the contiguous 48 United States, coastal waters, and wetland areas. This report is the first in a three-volume series and is intended for use by professional fishery biologists and water quality management personnel; Federal and State decision-makers and planners; and the general public.
